GRAPH 1

## ANNUAL RATE OF MORTALITY PER THOUSAND THE ORIGINAL REGISTRATION STATES BOTH SEXES: 1910

The values on which this graph is based may be found in column 4, page 54.

GRAPH 2

## ANNUAL AND MONTHLY RATES OF MORTALITY PER THOUSAND

THE ORIGINAL REGISTRATION STATES

MALES: 1901, 1910

FEMALES: 1901, 1910

The values on which these graphs are based may be found in column 4 on the following pages: 56, males, 1901; 58, males, 1910; 60, females, 1901; 62, females, 1910.

GRAPH 3

ANNUAL AND MONTHLY RATES OF MORTALITY PER THOUSAND

NEGROES IN THE ORIGINAL REGISTRATION STATES

MALES: 1901, 1910

FEMALES: 1901, 1910

The values on which these graphs are based may be found in column 4 on the following pages: 76, males, 1901; 80, males, 1910; 82, females, 1901; 86, females, 1910.

GRAPH 4

## ANNUAL AND MONTHLY RATES OF MORTALITY PER THOUSAND

MALES: 1901, 1910

WHITES IN CITIES OF THE ORIGINAL REGISTRATION STATES

FEMALES: 1901, 1910

The values on which these graphs are based may be found in column 4 on the following pages: 104, males, 1901; 106, males, 1910; 108, females, 1901; 110, females, 1910.

GRAPH 5

ANNUAL AND MONTHLY RATES OF MORTALITY PER THOUSAND

WHITES IN THE RURAL PART OF THE ORIGINAL REGISTRATION STATES

MALES: 1901, 1910

FEMALES: 1901, 1910

The values on which these graphs are based may be found in column 4 on the following pages: 112, males, 1901; 114, males, 1910; 116, females, 1901; 118, females, 1910.

GRAPH 6

## ANNUAL AND MONTHLY RATES OF MORTALITY PER THOUSAND

MALES: 1910      WHITES AND NEGROES IN THE ORIGINAL REGISTRATION STATES      FEMALES: 1910

The values on which these graphs are based may be found in column 4 on the following pages: 68, white males; 74, white females; 80, Negro males; 86, Negro females.

GRAPH 7

## ANNUAL AND MONTHLY RATES OF MORTALITY PER THOUSAND

WHITES IN CITIES AND RURAL PART OF THE ORIGINAL REGISTRATION STATES

MALES: 1910

FEMALES: 1910

The values on which these graphs are based may be found in column 4 on the following pages: 106, city males; 110, city females; 114, rural males; 118, rural females.

## PART V

TABLES OF LIFE ANNUITIES, ANNUAL PREMIUMS, SINGLE PREMIUMS, AND  
COMMUTATION COLUMNS BASED ON LIFE TABLES FOR WHITE  
MALES AND FOR WHITE FEMALES IN THE ORIGINAL  
REGISTRATION STATES: 1910

---

PART V.—TABLES OF LIFE ANNUITIES, ANNUAL PREMIUMS, SINGLE PREMIUMS,  
AND COMMUTATION COLUMNS BASED ON LIFE TABLES FOR WHITE MALES  
AND FOR WHITE FEMALES IN THE ORIGINAL REGISTRATION STATES: 1910.

PRACTICAL USES SERVED BY THESE TABLES.

93. This part consists of tables of life annuities and other tables useful in connection with problems involving life contingencies. Values of life table functions based on the rates of mortality experienced among white men and women in this country are needed frequently in legal and business practice. For example, in the settlement of estates and division of wills, the present values of life annuities based on one or more lives of different ages and sexes are often required. The only way to obtain this information is to consult the available life or mortality tables. Until the appearance of the United States Life Tables there were practically no reliable life tables available which faithfully represented mortality conditions as they now exist in the general population. In lieu of such tables it has been the practice to employ the American Experience Mortality Table, the Northampton, the Carlisle, or some of the English Life Tables. Since these tables differ materially from the United States Life Tables for white males and white females, the values obtained by their use were correspondingly in error. A direct comparison of the rate of mortality, expectation of life, and other functions by these tables may be made with various other tables based on the experience of life insurance companies by referring to Tables 85 to 89 on pages 226 to 235.

In addition to the uses mentioned above, these tables may be employed in the valuation of pension funds and for other purposes in connection with the setting up of pension systems where the mortality is likely to be in accordance with that of the general population. They may also be used to measure the present value of income and the present value of charitable bequests based upon the lives of individuals. The application of the tables in the latter case in connection with deductions in computing the income tax is obvious.

It is sometimes necessary in legal practice, when determining the measure of damages, to have the present value at a given rate of interest of a life annuity to a male or female of a given age. For this purpose these tables will be found particularly useful because they extend down to the infant ages, which usually is not the case in tables based on insurance experience.

LIFE ANNUITIES, NET PREMIUMS, COMMUTATION COLUMNS,  
AT DIFFERENT RATES OF INTEREST.

94. To meet the increasing need for accurate values of mortality functions based on the experience of the general population in this country, tables of this character are given in Part V. Two life tables were chosen for this purpose, one for white males in the original registration states, 1910, pages 68 and 69, and the other for white females in the original registration states, 1910, pages 74 and 75. Each of these tables is based on a population of about twelve millions and reported deaths of over half a million in the original registration states; they should, therefore, portray with great faithfulness the rates of mortality as they now exist among white males and white females in this country.

It is upon these life tables that the tabulated life annuities, net premiums, and commutation columns are based. They are divided into two sets, those for males in Tables 92 to 98, pages 298 to 311, and those for females in Tables 99 to 105, pages 312 to 325.

The values of the life annuities are given for each age at rates of interest 3,  $3\frac{1}{2}$ , 4, 5, and 6 per cent. The tabulated annuities give the present value of \$1 per year throughout life, the first payment to be made at once. An annuity of this character is called a life annuity due. The method of using these annuities is explained in section 83 in the Questions and Answers of Part I of this text, pages 47 and 48.

The tables of annuities are followed by tables of net single and net annual premiums per \$1,000 of ordinary whole life insurance at 3,  $3\frac{1}{2}$ , and 4 per cent.

To facilitate actuarial calculations, commutation columns are given at 3,  $3\frac{1}{2}$ , 4, 5, and 6 per cent. These columns include values of the six functions  $D_x$ ,  $N_x$ ,  $S_x$ ,  $C_x$ ,  $M_x$ ,  $R_x$ . They make it possible for the actuary to calculate all the values on single lives which would be required in practice.

The values given in this part are on one life. If values based on two or more lives are required, there is sufficient information contained in the tables to enable the actuary to make the necessary calculations. It would, of course, be desirable to have the life tables graduated to Makeham's formula, and thus facilitate the calculation of values on multiple lives; it has not been found feasible, however, to present such tables at this time.

TABLE 92

## LIFE ANNUITY DUE.

## WHITE MALES

PRESENT VALUE, AT EACH AGE AND VARIOUS RATES OF INTEREST, OF A LIFE ANNUITY OF ONE DOLLAR PER ANNUM, FIRST PAYMENT TO BE MADE AT ONCE, BASED ON LIFE TABLE FOR WHITE MALES IN THE ORIGINAL REGISTRATION STATES: 1910.<sup>1</sup>

## PART VI

### MATHEMATICAL THEORY OF CONSTRUCTION OF LIFE TABLES

---

## PART VI.—MATHEMATICAL THEORY OF CONSTRUCTION OF LIFE TABLES.

### DIVISION INTO THREE MAIN SECTIONS FOR CONSTRUCTION.

95. These life tables are constructed from the population and mortality returns of the Bureau of the Census; in some cases the birth registration returns have been employed. The construction may be broadly classified into three sections, the treatment varying greatly in these respective sections. The first section includes the early years of life, ranging from birth to about age 5; the second or middle range runs from about age 5 to about age 85; and the third range takes in the ages from about 85 to 115. Age 116 was assumed to be the limit of human life, and the tables are so calculated that the rate of mortality at age 115 is unity. Each of these sections presents its own peculiar problems which will be considered in detail.

### GRAPHICAL REPRESENTATION OF FLOW OF POPULATION.<sup>1</sup>

96. The work of analyzing the problems of life table construction is much simplified by the choice of a suitable graphical representation. This representation should show for each individual the date of birth, the age on any given date, the date of death, and the age at death. Various plans have been proposed to show graphically the above facts; of these the one described below will be employed.

DIAGRAM 1.—CONNECTION BETWEEN FLOW OF A POPULATION AND TIME AND AGE.

Rectangular axes OX and OT are chosen as in Diagram 1. OT is the *time axis* and OX the *age axis*, and the origin O is taken as some definite point or date

<sup>1</sup> The graphical representation and mathematical theory outlined in sections 96 to 106 are the outcome of a gradual development with which may be connected the names of a number of writers on mathematical statistics—Knapp, Zeuner, Becker, Lexis, Perozzo, and others. For a systematic treatment of this subject the reader is referred to *Wahrscheinlichkeitsrechnung*, by E. Czuber, vol. 2, p. 90. This work was freely consulted in preparing the above-mentioned sections.

in time. Then  $(t, x)$  represents the individual now aged  $x$  years who was born at B just  $t$  years after the time O. If the line PC is drawn through P perpendicular to the bisector of angle TOX it appears that  $OB = AC = t$  and  $OC = t + x = z$ . It is evident that  $z$  is the *current time* because P was born  $t$  years after the time O and is now  $x$  years of age. The figure also shows that P' was born  $t'$  years after the time O and is now  $x'$  years of age. Since P and P' are on the *same diagonal line*, it follows that at the time  $z$  they are both living, but are not of the same age. A line such as BP may be termed very properly the *life line* of the individual P. It starts at B with his birth and moves continuously to the right, and its length at any time represents his age. Three lines, particularly important in this method of graphical representation, are drawn through the point P; the one parallel to OT cuts OX at A, and OA is the age  $x$  at the time  $z$ ; the one parallel to OX cuts OT at B, and OB is the time of birth measured from the origin O; the line through P perpendicular to the bisector of angle TOX intersects OX at C, and OC represents the *present or current time*  $= z = t + x$ , measured from O. Consider the lines PA, PB, and PC all produced indefinitely, each dividing the plane in two regions; then another way of stating it is that all points to the left of the line PA represent persons *less than*  $x$  years of age, and all points to the right of PA persons *more than*  $x$  years of age; all points above PB represent persons born *before* the time  $t$ , and all points below PB persons born *after* the time  $t$ ; all points to the left of PC represent persons living *before* the time  $z$ , and all points to the right of PC persons living *after* the time  $z$ . When a person dies the life line comes to an end, and the aggregate of these end points of terminated life lines may be considered as representing an aggregate of the dead.

Suppose now a definite area, as some state or country, is fixed upon, and an origin, as January 1, 1910, selected, and all the individuals or persons born in that country represented by appropriate life lines in a diagram such as above described.

In Diagram 2 lines are drawn parallel to the axes a unit or year apart, and diagonal lines are also drawn, passing through the vertices of the unit squares and parallel to the bisector of the external angle. Let the vertical set be designated as the  $x$  lines, the horizontal as the  $t$  lines, and the diagonal as the  $z$  lines. The  $x$  and  $t$  lines divide the plane into unit squares, the  $t$  and  $z$  and the  $z$  and  $x$  lines into elemen-

tary parallelograms. A study of what happens in each of these elementary areas will throw a great deal of light on the flow of a population or an aggregate of individuals.

The upper triangle of the upper left-hand unit square, containing the origin in Diagram 2, includes individuals born in 1910 and living or dying in the age interval 0-1. Four life lines are drawn representing individuals born January 1, April 1, July 1, and October 1, in the calendar year 1910. The arrow-heads ending on the first diagonal line show that on January 1, 1911, they were, respectively, 1 year, 9

months, 6 months, and 3 months old. If life lines were drawn to represent every individual born in the world during the calendar year 1910, the variable points tracing the life lines of those living on January 1, 1911, would all lie at that time on the first diagonal  $z$  line and a count or enumeration of the population of the world in the age interval 0-1 on this date would comprehend or include every life line actually reaching this diagonal. Deaths in this aggregate would correspond to the life lines *ending* within the triangle and not extending to the diagonal line.

DIAGRAM 2.—FLOW OF A POPULATION MEASURED BY LIFE LINES.

If all the births in the world during the next calendar year, 1911, were entered in the form of life lines and a census taken January 1, 1912, the population would include all living individuals between 0 and 2 years of age, that is, living in the age intervals 0-1 and 1-2. The diagram plainly shows that a count of life lines extending to the lower half of the second diagonal would give the 0-1 population, and a count of the life lines extending to the upper half of the second diagonal would give the population living in the age interval 1-2. The first group is seen, by following the life lines back to the OT axis, to have been born in 1911, the second group in 1910.

It is evident that the process above described is one of continuous flow and that the *front* of the moving diagonal line corresponds to the persons alive *now* who were born since January 1, 1910. The plane may be considered as filled, first, with an aggregate of points, the *ends* of life lines which have ended or broken off, representing the number of deaths, and the ages and the dates at which deaths have occurred; and, second, life lines which have not ended or broken

off and which represent various things, such as the number of persons living at the present moment, their dates of birth, and their ages. All the life lines, those broken off and those unbroken, represent the number born.

#### MATHEMATICAL THEORY OF FLOW OF POPULATION.

97. A sufficient explanation has now been made of the graphical representation to pass to the general theory of the movement or flow of a population in time. If a large group or aggregate is taken, it may be assumed that the births, counting from a given time, are continuous; likewise for the deaths. Let the function  $F(t, x)$  denote the number of persons, born after the fixed date selected as the origin and before the time  $t$ , who are living at age  $x$ . This is a definite aggregate as soon as an area of observation has been chosen. For example, all the persons born in the world after January 1, 1800, and before January 1, 1860, who reached age 35 would be represented by  $F(60, 35)$ , if January 1, 1800, were selected as the origin and the entire world were the area under consideration.

Taking the axis  $y$  perpendicular to the  $(t, x)$  plane, Diagram 4, the function  $y = f(t, x)$  is erected at each point in the plane, the end points thus describing a surface. The perpendiculars erected on any curve as  $x = g(t)$  in the plane will form a cylindrical surface, and it is evident that the integral

$$\int_{P_1 P_2} f(t, x) dt = \int_{t_1}^{t_2} f(t, x) dt = \int_{t_1}^{t_2} f[t, g(t)] dt \quad (4)$$

can be represented by the shaded projection  $t_1 R_1 t_2 R_2$  on the YT plane of the cylindrical surface  $P_1 S_1 P_2 S_2$ . It thus appears that the projection of the cylindrical surface on the YT plane represents the aggregate or number of persons born in the interval  $(t_1, t_2)$  who attained the corresponding ages along the curve  $x = g(t)$  between the age limits  $P_1$  and  $P_2$ . This same number would also be given by enumerating the life lines starting between  $t_1$  and  $t_2$  and intersecting the curve  $x = g(t)$ .

Another important result can be obtained by an application of Green's theorem in space of two dimensions. It may be stated as follows:

*The surface integral of  $\varphi(t, x)$  extended over any simple closed area  $A$  is equal to the line integral of  $f(t, x)$  taken along the boundary of  $A$  in the counterclockwise direction.*

DIAGRAM 5.—NUMBER OF DEATHS IN CLOSED AREA.

Let  $t_1$  and  $t_2$  be tangent to the boundary of the simple closed area  $A$  at points  $T_1$  and  $T_2$ , respectively, and  $x = g(t)$  be the equation of the left side of the boundary of  $A$  between the points of tangency and  $x = h(t)$ , the equation of the right side. Since

$$\varphi(t, x) = -\frac{\partial f(t, x)}{\partial x},$$

$$\begin{aligned} \iint_A \varphi(t, x) dt dx &= - \int_{t_1}^{t_2} dt \int_{g(t)}^{h(t)} \frac{\partial f(t, x)}{\partial x} dx \\ &= - \int_{t_1}^{t_2} f[t, h(t)] dt + \int_{t_1}^{t_2} f[t, g(t)] dt \\ &= \int_{t_1}^{t_2} f[t, g(t)] dt + \int_{t_2}^{t_1} f[t, h(t)] dt, \end{aligned} \quad (5)$$

which is evidently equal to the integral of  $f(t, x)$  with respect to  $t$  extended around the boundary in the positive direction.

On account of the definition of  $\varphi(t, x)$  the integral of the function extended over the surface area  $A$  is equal to the number of deaths falling within the area. It is therefore equal to the number of life lines starting between  $t_1$  and  $t_2$  and ending somewhere within the area  $A$ .

#### AGGREGATE OF THOSE SURVIVING TO SAME AGE.

99. It is now possible to define some of the more important aggregates of the living and dead and to establish equations connecting them. One of the most useful aggregates of the living for purposes of life table construction is that of persons of the *same age*. This aggregate is readily observed in the graphical representation already explained.

DIAGRAM 6.—BIRTH AND TIME INTERVALS COVERED BY THOSE SURVIVING TO SAME AGE.

Referring to Diagram 6, the enumeration of life lines crossing  $E_1 E_2$  would give the number of persons born in the interval  $(t_1, t_2)$  who actually lived to age  $x$ . It is evident they did not attain this age at the same time; the figure shows that the first one, born at time  $t_1$ , attained age  $x$  at time

$$z_1 = t_1 + x$$

and the last born at time  $t_2$  attained age  $x$  at time

$$z_2 = t_2 + x.$$

By subtraction

$$z_2 - z_1 = t_2 - t_1,$$

whence it appears that if the birth interval is one year the same is true of the interval of time between which the first and last members of the aggregate attain age  $x$ . This aggregate, by the first theorem in section 98, may be represented analytically by the integral

$$E_x^{t_1/t_2} = \int_{t_1}^{t_2} f(t, x) dt. \quad (6)$$

This is a special case where the curve  $x = g(t)$  reduces to a line,  $x = \text{constant}$ , parallel to the time axis. In the particular case where the constant is zero the aggregate

$$E_0^{t_1/t_2} = \int_{t_1}^{t_2} f(t, 0) dt \quad (7)$$

is equal to the number born in the interval of time  $(t_1, t_2)$ . This is a statistical aggregate and would be derived directly from accurate birth registration. Unfortunately, for most areas, reliable birth registration statistics were not available for the construction of the present life tables, and the number of births had to be obtained by another method explained in the text. The function  $E_x^{t_1/t_2}$  is in general not a statistical aggregate and is not given in the publications of the bureau. Its value must be derived from other statistical aggregates which have been obtained by actual enumeration.

#### AGGREGATE OF THOSE LIVING AT SAME TIME.

100. Another important aggregate of the living consists of those persons living at the *same time*. It is made up of individuals of different ages and is a statistical aggregate, that is, ordinarily obtainable from collected and published data.

DIAGRAM 7.—BIRTH AND AGE INTERVALS COVERED BY THOSE LIVING AT SAME TIME.

This aggregate would be determined by the number of life lines, shown in Diagram 7, crossing the diagonal line  $P_1P_2$ , among those who were born in the time interval  $(t_1, t_2)$ . The diagram shows that

$$z = t + x$$

is the date of observation, and a count, enumeration, or census taken at time  $z$  along the line  $P_1P_2$  would give the population or number of persons then living in the age interval  $(x_1, x_2)$ . The youngest person in this aggregate is aged

$$x_1 = z - t_2,$$

and the oldest

$$x_2 = z - t_1,$$

and the general relation existing between the time of enumeration  $z$ , time of birth  $t$ , and age at enumeration is

$$x = z - t.$$

This is the equation of the diagonal line, and employing the first theorem in section 98 with  $g(t) = z - t$ , the following is the result:

$$P_z^{x_1/x_2} = \int_{P_1P_2} g(t, x) dt = \int_{t_1}^{t_2} f(t, z - t) dt. \quad (8)$$

This integral has for its value the population at time  $z$  of all persons in the aggregate living between

ages  $x_1 = z - t_2$  and  $x_2 = z - t_1$  who were born in the time interval  $(t_1, t_2)$ . By subtraction

$$x_2 - x_1 = t_2 - t_1,$$

whence it appears that the age interval included in the aggregate is the same as the time of birth interval; in particular, if the latter is one year the age interval will be one year. This aggregate is taken every ten years in this country and the results tabulated and published by the Bureau of the Census. An enumeration was made on April 15, 1910, and the next preceding one on June 1, 1900.<sup>1</sup> The symbol  $P_z^{x_1/x_2}$  will be employed to represent explicitly the population between ages  $x_1$  and  $x_2$  enumerated at time  $z$ , born in the interval  $(t_1, t_2)$ , where  $t_1 = z - x_2$  and  $t_2 = z - x_1$ . For example, if the origin is June 1, 1870, then  $P_{40}^{26/27}$  would denote the number of persons living on June 1, 1910, between ages 26 and 27; the youngest in the aggregate was born June 1, 1884, and the oldest June 1, 1883, and all the others between these dates.

#### FIRST AGGREGATE OF THE DEAD: TYPE ONE.

101. There are three mortality or death aggregates to which attention will be called. The first aggregate of the dead,  $D_{x_1/x_2}^{t_1/t_2}$ , referred to as *type one*, includes those persons who were born in the time interval  $(t_1, t_2)$  and who lived to age  $x_1$ , but not to age  $x_2$ , that is, died in the age interval  $(x_1, x_2)$ .

DIAGRAM 8.—AGGREGATE OF THE DEAD WHO WERE BORN IN SAME TIME INTERVAL AND WHO DIED IN SAME AGE INTERVAL.

Let the dots or points in the area  $D_{x_1/x_2}^{t_1/t_2}$  represent the ends or terminations of life lines which started in time interval  $(t_1, t_2)$  and ended in age interval  $(x_1, x_2)$ ; then a count of these points would correspond to the registration of deaths, occurring after time  $z_1$  and before time  $z_2$ , of persons between ages  $x_1$  and  $x_2$  who were born in the time interval  $(t_1, t_2)$ . The first death at  $f$  occurs at the time

$$z_1 = t_1 + x_1$$

and the last at  $b$  at the time

$$z_2 = t_2 + x_2.$$

Since

$$z_2 - z_1 = (t_2 - t_1) + (x_2 - x_1),$$

it appears that if the generation or birth interval

<sup>1</sup> The last enumeration was made as of Jan. 1, 1929.

$(t_1, t_2)$  and the age interval  $(x_1, x_2)$  are each *one* year, the observation interval  $(z_1, z_2)$  is *two* years. For example, if the persons in this aggregate were born in the calendar year 1880 and died in the age interval (25, 26), that is, after reaching age 25 but before attaining age 26, the deaths must have been distributed over the *two* calendar years 1905 and 1906.

The second theorem in section 98, when applied to the area  $D_{z_1/z_2}^{t_1/t_2}$  leads to the following result:

$$\begin{aligned} D_{z_1/z_2}^{t_1/t_2} &= \int_{t_1}^{t_2} \int_{x_1}^{x_2} \varphi(t, x) dt dx \\ &= \int_{t_1}^{t_2} f(t, x_1) dt - \int_{t_1}^{t_2} f(t, x_2) dt \\ &= E_{x_1}^{t_1/t_2} - E_{x_2}^{t_1/t_2}. \end{aligned} \quad (9)$$

In taking the integral along the boundary of area  $D_{z_1/z_2}^{t_1/t_2}$  Diagram 8, in the direction indicated by the arrows, it is evident that the integrals along the lines  $df$  and  $ab$  vanish, because they are normal to the time axis. The result

$$D_{z_1/z_2}^{t_1/t_2} = E_{x_1}^{t_1/t_2} - E_{x_2}^{t_1/t_2} \quad (10)$$

might have been inferred at once because the number of deaths must be the excess of life lines in generation  $(t_1, t_2)$  which cross the  $x_1$  line over those which cross the  $x_2$  line.

#### SECOND AGGREGATE OF THE DEAD: TYPE TWO.

102. The second aggregate of the dead,  $D_{z_1/z_2}^{t_1/t_2}$ , referred to as *type two*, includes persons in the generation  $(t_1, t_2)$  who die after the time  $z_1$  and before the time  $z_2$ .

DIAGRAM 9.—AGGREGATE OF THE DEAD WHO WERE BORN IN SAME TIME INTERVAL AND WHO DIED IN SAME TIME INTERVAL.

Diagram 9 shows that the deaths are distributed in the age interval  $(x_1, x_2)$ , where

$$x_1 = z_1 - t_1$$

and

$$x_2 = z_2 - t_1.$$

Since

$$x_2 - x_1 = (t_2 - t_1) + (z_2 - z_1),$$

it appears that the age interval will cover a period of *two* years if the generation and observation periods are each *one* year. For example, when the observation period for deaths is the calendar year 1910 and is confined to persons born in the calendar year 1880, the ages of the decedents will be from 29 to 31. By means of the second theorem in section 98 the surface integral extended over the area  $D_{z_1/z_2}^{t_1/t_2}$  is equal to the boundary integral along  $abcd$ , the integrals along  $ab$  and  $cd$  vanishing as these lines are normal to the time axis. This gives, since  $x = z_1 - t$  on  $ad$  and  $x = z_2 - t$  on  $bc$ ,

$$\begin{aligned} D_{z_1/z_2}^{t_1/t_2} &= \int_{t_1}^{t_2} \int_{z_1-t}^{z_2-t} \varphi(t, x) dt dx = \int_{t_1}^{t_2} dt \int_{z_1-t}^{z_2-t} -\frac{\partial f(t, x)}{\partial x} dx \\ &= \int_{t_1}^{t_2} f(t, z_1 - t) dt - \int_{t_1}^{t_2} f(t, z_2 - t) dt \\ &= P_{z_1}^{z_1/z_2} - P_{z_2}^{z_1/z_2}. \end{aligned} \quad (11)$$

The expression for  $D_{z_1/z_2}^{t_1/t_2}$  in terms of population aggregates could be verified at once from the diagram, because the terminated life lines or deaths in  $D_{z_1/z_2}^{t_1/t_2}$  must be the excess of the life lines of generation  $(t_1, t_2)$  which cross the  $z_1$  line over those which cross the  $z_2$  line.

#### THIRD AGGREGATE OF THE DEAD: TYPE THREE.

103. The third aggregate of the dead,  $D_{z_1/z_2}^{z_1/z_2}$ , referred to as *type three*, includes those persons who die within the period  $(z_1, z_2)$  and in the age interval  $(x_1, x_2)$ .

Diagram 10 shows that

$$t_1 = z_1 - x_2$$

and

$$t_2 = z_2 - x_1,$$

whence

$$t_2 - t_1 = (z_2 - z_1) + (x_2 - x_1),$$

and it follows that the generation interval is the sum of the observation period and the age interval. If the last two are *one* year intervals, the generation interval will cover *two* years. In other words, if the deaths for a calendar year are arranged by age intervals of one year, the persons dying in any age interval are distributed over two calendar years of birth. For example, the deaths for the calendar year 1916 of persons in the age interval 49-50 are distributed over two calendar years of birth, namely, 1866 and 1867.

DIAGRAM 10.—AGGREGATE OF THE DEAD WHO DIED IN SAME TIME INTERVAL AND IN SAME AGE INTERVAL.

The integral expressing the value of  $D_{x_1/z_1}^{x_2/z_2}$  is by the second theorem in section 98,

$$\begin{aligned} D_{x_1/z_1}^{x_2/z_2} &= \int_{x_1}^{x_2} \int_{z_1-x}^{z_2-x} \varphi(t, x) dx dt \\ &= E_{x_1}^{t_1 + (x_2 - x_1)/t_2} - P_{x_2}^{x_1/z_2} \\ &\quad - E_{x_2}^{t_2 + (x_2 - x_1)/t_2} + P_{x_1}^{x_1/z_2} \\ &= E_{x_1}^{z_1 - x_1/z_2 - x_1} - P_{x_2}^{x_1/z_2} \\ &\quad - E_{x_2}^{z_2 - x_2/z_2 - x_2} + P_{x_1}^{x_1/z_2}, \end{aligned} \quad (12)$$

This result may also be obtained by breaking up the parallelogram  $adef$ , Diagram 11, into the upper triangle  $fne$ , the middle rectangle  $mdnf$ , and the lower triangle  $adm$ , and applying the second theorem of section 98 directly to each part and taking the sum. The integrals are as follows:

$$\begin{aligned} D_{x_1/z_1}^{x_2/z_2} &= \int_{fne} \varphi(t, x) dt dx + \int_{mdnf} \varphi(t, x) dt dx + \int_{adm} \varphi(t, x) dt dx \\ &= \int_{z_1-x_2}^{z_1-x_1} dt \int_{z_1-t}^{x_2} -\frac{\partial f(t, x)}{\partial x} dx + \int_{z_1-x_1}^{z_2-x_1} dt \int_{x_1}^{x_2} -\frac{\partial f(t, x)}{\partial x} dx \\ &\quad + \int_{z_2-x_1}^{z_2-x_2} dt \int_{x_1}^{z_2-t} -\frac{\partial f(t, x)}{\partial x} dx \\ &= \int_{z_1-x_2}^{z_1-x_1} [f(t, z_1-t) - f(t, x_2)] dt + \int_{z_1-x_1}^{z_2-x_1} [f(t, x_1) - f(t, x_2)] dt \\ &\quad + \int_{z_2-x_1}^{z_2-x_2} [f(t, x_1) - f(t, z_2-t)] dt \\ &= \int_{z_1-x_1}^{z_2-x_1} f(t, x_1) dt - \int_{z_1-x_1}^{z_2-x_1} f(t, z_2-t) dt - \int_{z_1-x_2}^{z_1-x_1} f(t, x_2) dt \\ &\quad + \int_{z_1-x_2}^{z_1-x_1} f(t, z_1-t) dt \\ &= E_{x_1}^{z_1-x_1/z_2-x_1} - P_{x_2}^{x_1/z_2} - E_{x_2}^{z_2-x_2/z_2-x_2} + P_{x_1}^{x_1/z_2}. \end{aligned}$$

DIAGRAM 11.—INTEGRATION TO DETERMINE NUMBER OF DEAD IN TYPE THREE AGGREGATE.

From Diagram 10 it can be seen that the life lines which terminate in  $D_{x_1/z_1}^{x_2/z_2}$  entered through  $af$  and  $fe$ , and that the life lines which passed through it left through  $ad$  and  $de$ . Accordingly, the life lines which terminate in this area must be expressed by

$$D_{x_1/z_1}^{x_2/z_2} = (P_{x_1}^{x_1/z_2} + E_{x_1}^{z_1-x_1/z_2-x_1}) - (P_{x_2}^{x_1/z_2} + E_{x_2}^{z_2-x_2/z_2-x_2}),$$

which agrees with equation (12).

In the special case where the observation period and the age interval are each *one* year, this reduces to

$$D_{x/z+1}^{z/z+1} = E_x^{t+1} - E_{x+1}^{t+1} + P_z^{z/z+1} - P_{z+1}^{z/z+1} \quad (13)$$

and the generation interval covers *two* years. This relation might have been written down directly by referring to parallelogram  $adef$  in Diagram 12.

#### RELATIONS BETWEEN AGGREGATES OF THE LIVING AND OF THE DEAD.

104. It will be observed in the case of the three types of aggregates of the dead that, when any two of the three variables  $t$ ,  $x$ , and  $z$  are given a unit increment, the remaining one takes on an increment of double that amount.

Diagram 12 shows the two types of aggregates of the living,

$$E_x^{t/t+1} \quad \text{and} \quad P_z^{z/z+1},$$

and the three types of aggregates of the dead:

$$\begin{aligned} \text{Type one, } D_{x/z+1}^{t/t+1} \text{ in } abdf \\ = D_{x,z+1,t} + D_{x+1,t+1,z+1} \text{ or } D_\alpha + D_\beta; \end{aligned}$$

$$\begin{aligned} \text{Type two, } D_{z+1/t+2}^{t/t+1} \text{ in } abcd \\ = D_{z+1,t+1,z+1} + D_{x+1,t+2,t} \text{ or } D_\beta + D_\gamma; \end{aligned}$$

$$\begin{aligned} \text{Type three, } D_{x/z+1}^{z/z+1} \text{ in } adef \\ = D_{z,t,x+1} + D_{z,t+1,t} \text{ or } D_\delta + D_\alpha. \end{aligned}$$

The last,  $D_{x/z+1}^{z/z+1}$ , is the only statistical aggregate of the dead available for this country; it is given in the form of deaths for the calendar year according to age intervals. If, in addition, these deaths were classified according to year of birth, then the aggregates of the dead in each elementary triangle would be known, and it would be a simple matter to obtain the probability of living and hence the rate of mortality at each age. For example, if  $D_\alpha$  and  $D_\beta$  were known, Diagram 12 shows that

$$E_x^{t/t+1} = D_\alpha + P_{z+1}^{z/z+1}$$

and

$$P_{z+1}^{z/z+1} = D_\beta + E_{z+1}^{t/t+1}$$

whence

$$\frac{E_{z+1}^{t/t+1}}{E_x^{t/t+1}} = p_z^{t/t+1} = \frac{P_{z+1}^{z/z+1} - D_\beta}{P_{z+1}^{z/z+1} + D_\alpha}$$

and

$$q_z^{t/t+1} = 1 - p_z^{t/t+1} = \frac{D_\alpha + D_\beta}{P_{z+1}^{z/z+1} + D_\alpha} \quad (14)$$

DIAGRAM 12.—RELATIONS BETWEEN AGGREGATES OF THE LIVING AND OF THE DEAD.

#### EXPRESSION OF RATE OF MORTALITY IN TERMS OF STATISTICAL AGGREGATES.

105. In order to calculate the rapidly changing rate of mortality for ages under 5 years it is necessary to take into account the force of mortality which is defined as follows,  $\xi$  being a variable measured from  $x$ :

$$\mu_{x+\xi} = -\frac{1}{l_{x+\xi}} \frac{dl_{x+\xi}}{d(x+\xi)} = -\frac{d \log l_{x+\xi}}{d(x+\xi)} = -\frac{d \log l_{x+\xi}}{d\xi}. \quad (15)$$

Therefore,

$$-\int_0^\xi \mu_{x+\xi} d\xi = \int_0^\xi d \log l_{x+\xi} = \log l_{x+\xi} - \log l_x = \log {}_\xi p_x$$

and

$${}_x p_x = e^{-\int_0^\xi \mu_{x+\xi} d\xi} \quad \text{and} \quad {}_x q_x = 1 - e^{-\int_0^\xi \mu_{x+\xi} d\xi}.$$

In particular, when  $\xi = 1$ ,

$$p_x = e^{-\int_0^1 \mu_{x+\xi} d\xi} \quad \text{and} \quad q_x = 1 - e^{-\int_0^1 \mu_{x+\xi} d\xi}. \quad (16)$$

By referring to Diagram 13 it will be observed that an application of the second theorem in section 98 leads to the equation

$$D_{x/z+1}^{z/z+1} = E_x^{z_1-z/z_1-z} - P_{z_1}^{z/z+1} - E_{x+\xi}^{z_1-z-\xi/z_1-z-\xi} + P_{z_1}^{z/z+1},$$

or, dropping superscripts, setting

$$\delta_{x/z+\xi} = P_{z_1}^{x/z+\xi} - P_{z_1}^{x/z+\xi}, \quad (17)$$

and solving for  $E_{x+\xi}$ , to

$$E_{x+\xi} = E_x - \delta_{x/z+\xi} - D_{x/z+\xi}. \quad (18)$$

DIAGRAM 13.—VARIATION OF AGGREGATES OF THE LIVING AND TYPE THREE AGGREGATES OF THE DEAD WITH AGE AND TIME.

The number of deaths in the differential strip  $dD_{x/z+\xi}$  is the product of the number exposed, the

since, by assumption, the population  $P_{x/z+1}^{z/z+1}$  varies uniformly from  $z$  to  $z+1$ . If now with respect to the type three parallelogram  $adef$  the additional assumption is made that the number of deaths in the age interval  $(x, x+1)$  in the lower triangle,  $D_a$ , is equal to the number of deaths in the upper triangle,  $D_b$ , or, in other words, that the deaths in each age interval of any calendar year are equally divided between the two generations to which they belong, then

$$D_a = D_b = \frac{1}{2} D_{x/z+1}^{z/z+1}, \quad (23)$$

and it follows directly that

$$q_x^{z/z+1} = \frac{D_{x/z+1}^{z/z+1}}{P_{z+\frac{1}{2}}^{z/z+1} + \frac{1}{2} D_{x/z+1}^{z/z+1}} \\ = \frac{D_{x/z+1}^{z/z+1} / P_{z+\frac{1}{2}}^{z/z+1}}{1 + \frac{1}{2} D_{x/z+1}^{z/z+1} / P_{z+\frac{1}{2}}^{z/z+1}} = \frac{m_x}{1 + \frac{1}{2} m_x}, \quad (24)$$

where  $m_x$ , the central death rate, is defined as the ratio of the deaths during the year to the population in the middle of the year. This is the usual formula employed to calculate the rate of mortality from the statistical aggregates, and it is now clear what assumptions are implied. It is also evident that the formula can not be applied during the early years of life, because  $D_a$  and  $D_b$  are not even approximately equal under age 5.

#### CALCULATION OF NUMBER OF BIRTHS.

106. In order to employ equations (18) and (22) to calculate the rate of mortality during the first five years of life it is necessary to know the number of births,  $E_0$ . Unfortunately, birth registration statistics for most of the areas for which life tables were to be constructed were not sufficiently reliable for this purpose, and it was necessary to determine the number of births from the population and mortality statistics. The method employed is explained by considering the actual process for males in the state of New York. Table 106 gives the reported deaths in the years 1909, 1910, and 1911 for certain age intervals under 5 years.

Table 106

| NUMBER OF REPORTED DEATHS AMONG MALES IN THE STATE OF NEW YORK USED IN COMPUTING NUMBER OF BIRTHS. |                                     |       |       |     |     |
|----------------------------------------------------------------------------------------------------|-------------------------------------|-------|-------|-----|-----|
| Calendar year in which death occurs.                                                               | Age interval in which death occurs. |       |       |     |     |
|                                                                                                    | 0-1                                 | 1-2   | 2-3   | 3-4 | 4-5 |
| 1909                                                                                               | 14,569                              |       |       |     |     |
| 1910                                                                                               | 15,234                              | 3,401 |       |     |     |
| 1911                                                                                               | 14,040                              | 2,993 | 1,320 |     |     |
| 1912                                                                                               | 13,746                              | 2,929 | 1,263 | 725 |     |
| 1913                                                                                               | .....                               | 2,973 | 1,305 | 803 | 615 |

When these deaths of type  $D_{x/z_2}^{z_1/z_2}$  are represented graphically and the numbers inserted in the corresponding parallelograms, the results are as shown in Diagram 15.

DIAGRAM 15.—GRAPHIC REPRESENTATION OF NUMBER OF DEATHS GIVEN IN TABLE 106.

From the diagram it appears that 14,569 males died under 1 year in 1909, that 2,929 died in 1912 aged 1 year last birthday, 615 died in 1913 aged 4 last birthday, and so on. These aggregates are of type  $D_{z_1/z_2}$  described in section 103, and it will be observed that there are *two* generations corresponding to the deaths in each calendar year. The numbers at the left margin show the calendar year of birth and also the calendar year belonging to each strip beginning at the left-hand edge and running diagonally up and to the right.

The next problem is to determine for each  $D_{z_1/z_2}$  the number of deaths belonging to the later generation and to the earlier generation, respectively. For example, how many of the 14,569 decedents in 1909 under 1 year were born in 1909, the later year, and how many in 1908, the earlier year?

**PERCENTAGE OF DECEDENTS BORN IN EARLIER AND LATER CALENDAR YEARS DERIVED FROM GERMAN MORTALITY STATISTICS.**

107. This question was first answered by investigating the mortality statistics of the German Empire, where, for many states, the deaths are reported for the calendar year by single years of age and by calendar year of birth. On pages 10\* to 13\* of Statistik des Deutschen Reichs, Band 200, there are several tables, based on the actual enumeration of a large number of deaths, showing in graduated form the percentage of deaths belonging to each of the two years of birth. Sections of these tables are reproduced here.

**Table 107**

| GRADUATED PERCENTAGES OF DEATHS IN CALENDAR YEAR ACCORDING TO LATER AND EARLIER CALENDAR YEARS OF BIRTH FOR FIRST TEN YEARLY AGE INTERVALS, BASED ON DEATHS IN PRUSSIA IN YEARS 1901-1905. |                                                              |                                                      |           |                                                              |                                                        |           |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|------------------------------------------------------|-----------|--------------------------------------------------------------|--------------------------------------------------------|-----------|
| Age interval in which death occurs.                                                                                                                                                        | Difference between calendar year of death and year of birth. | Percentage of decedents born in later calendar year. |           | Difference between calendar year of death and year of birth. | Percentage of decedents born in earlier calendar year. |           |
|                                                                                                                                                                                            |                                                              | Males.                                               | Females.  |                                                              | Males.                                                 | Females.  |
|                                                                                                                                                                                            |                                                              | Per cent.                                            | Per cent. |                                                              | Per cent.                                              | Per cent. |
| 0-1                                                                                                                                                                                        | 0                                                            | 71.34                                                | 70.38     | 1                                                            | 28.66                                                  | 29.62     |

| 7-8                                                                                                                                                                                        | 7                                                            | 51.29                                                | 50.43     | 8                                                            | 48.71                                                  | 49.57     |
| 8-9                                                                                                                                                                                        | 8                                                            | 51.10                                                | 50.22     | 9                                                            | 48.90                                                  | 49.78     |
| 9-10                                                                                                                                                                                       | 9                                                            | 50.80                                                | 50.23     | 10                                                           | 49.20                                                  | 49.77     |

Referring to Diagram 15, it may be said that if  $D_{z/z+1}$ , or type three parallelogram, is divided into its lower and upper elementary triangles the above Table 107 gives the values of ratios of the deaths in the lower and upper triangles, respectively, to the deaths in the parallelogram. Accordingly, when the number of deaths in the parallelogram is known, the

numbers in the elementary triangles can be obtained by applying the above ratios or percentages.

A similar investigation of the returns of 20 states in 1910<sup>1</sup> and of 14 states in 1911<sup>2</sup> gives the following percentages of deaths in the calendar year falling in the later year of birth:

**Table 108**

| Age interval in which death occurs. | Difference between calendar year of death and year of birth. | PERCENTAGE OF DECEDENTS WHO WERE BORN IN LATER CALENDAR YEAR. |           |                 |           |
|-------------------------------------|--------------------------------------------------------------|---------------------------------------------------------------|-----------|-----------------|-----------|
|                                     |                                                              | Deaths in 1910.                                               |           | Deaths in 1911. |           |
|                                     |                                                              | Males.                                                        | Females.  | Males.          | Females.  |
|                                     |                                                              | Per cent.                                                     | Per cent. | Per cent.       | Per cent. |
| 0-1                                 | 0                                                            | 72.13                                                         | 71.01     | 72.88           | 71.73     |
| 1-2                                 | 1                                                            | 60.81                                                         | 60.59     | 63.34           | 63.40     |

| 3-4                                 | 3                                                            | 51.74                                                         | 53.49     | 54.46           | 54.40     |
| 4-5                                 | 4                                                            | 53.31                                                         | 52.91     | 53.21           | 53.92     |
| 5-6                                 | 5                                                            | 51.44                                                         | 50.05     | 54.90           | 52.32     |
| 6-7                                 | 6                                                            | 51.16                                                         | 50.27     | 52.02           | 51.91     |
| 7-8                                 | 7                                                            | 51.41                                                         | 48.54     | 53.59           | 52.03     |
| 8-9                                 | 8                                                            | 50.55                                                         | 49.24     | 51.10           | 51.33     |
| 9-10                                | 9                                                            | 49.50                                                         | 51.57     | 51.39           | 55.13     |

These values have not been graduated and are accordingly not so smooth in their progression as those shown in Table 107. However, the tendency and general range is about the same.

**METHOD EMPLOYED TO VERIFY THESE PERCENTAGES.**

108. In order to test these ratios by returns made in this country the following method was employed. Let  $d_1, d_2, d_3, \dots, d_n$  represent the deaths occurring in the corresponding areas in Diagram 16.

**Diagram 16.—Division of Elementary Parallelogram into Months of Age.**

<sup>1</sup> Statistik des Deutschen Reichs, Band 246, pp. 67-69.

<sup>2</sup> Ibid, Band 256, pp. 65-67.

Evidently if the deaths are assumed to be evenly distributed in these elementary strips,  $\frac{23}{24}d_1$  occur among the 1910 generation and  $\frac{1}{24}d_1$  among the 1909 generation. The distribution of  $d_2$  would be  $\frac{21}{24}d_2$  for 1910 and  $\frac{3}{24}d_2$  for 1909, and similarly for the other elementary strips. This leads to the following formula for the number of deaths in the lower triangle *adj*:

$$\frac{1}{24} \sum_{n=1}^{n=12} (25-2n)d_n = \frac{23d_1 + 21d_2 + 19d_3 + \cdots + d_{12}}{24}. \quad (25)$$

When the strips are taken as weeks the formula becomes

$$\frac{1}{104} \sum_{n=1}^{n=52} (105-2n)d_n = \frac{103d_1 + 101d_2 + \cdots + d_{52}}{104}, \quad (26)$$

and when the strips are taken as days it becomes

$$\frac{1}{730} \sum_{n=1}^{n=365} (731-2n)d_n = \frac{729d_1 + 727d_2 + \cdots + d_{365}}{730}. \quad (27)$$

The formula can easily be derived in a similar manner for any combination of days, weeks, months, or other intervals. It is evident that the narrower the elementary strip the better will be the approximation to the true value. The percentage itself is, of course, obtained by dividing formulas (25), (26), and (27) by the total number of deaths in the parallelogram. For monthly strips the formula for the percentage born in the *later* calendar year is

$$\frac{\frac{1}{24} \sum_{n=1}^{n=12} (25-2n)d_n}{\sum_{n=1}^{n=12} d_n} = \frac{1}{24} \frac{23d_1 + 21d_2 + \cdots + d_{12}}{d_1 + d_2 + \cdots + d_{12}}. \quad (28)$$

For every year since 1900, with the exception of 1902, 1903, and 1904, mortality statistics by sex for each month of age during the first year of life are available for the original registration states;<sup>1</sup> for the calendar year 1910 this information is given by months of age through the second year of life, although not for males and females separately, for the registration area

<sup>1</sup> For the years 1900, 1901, and 1905 this information is given on pp. 630 to 660 of Mortality Statistics, 1908; for the years 1906, 1907, 1908, and 1909, on pp. 780 to 792 of Mortality Statistics, 1909; for the year 1910, on pp. 598-599 of Mortality Statistics, 1910. After 1910 these statistics were obtained from manuscript.

of 1910.<sup>2</sup> Numerous tests were made by the above method with these statistics and the percentages found to be in substantial agreement for the first and second years with those derived from the German statistics. The percentage factors for decedents born in the later calendar year among native white, both parents native, derived from equation (28) applied to total deaths by months under 1 year for the calendar years 1900 to 1901 and 1905 to 1910, are for males 72.12 and for females 70.65. The factor for age interval 1-2 derived from both sexes in the registration area in 1910 is 59.68. The factor for Ohio is 58.84 and for Pennsylvania 59.09. No statistics are given, however, which could be employed to test the percentages for the third, fourth, and fifth years of life.

#### PERCENTAGES ADOPTED AND CALCULATION OF NUMBER OF BIRTHS FROM POPULATION AND DEATH STATISTICS.

109. As a result of the investigations just described the following percentages were chosen as representing mortality distribution in this country during the first five years of life. It will be observed that a small variation one way or the other in the choice of these figures would make very little difference in the results obtained by their use in deriving the number of births in the various areas for which life tables are constructed.

Table 109

| PERCENTAGES OF DEATHS IN CALENDAR YEAR ACCORDING TO <i>LATER</i> AND <i>EARLIER</i> YEARS OF BIRTH FOR FIRST FIVE YEARLY AGE INTERVALS, EMPLOYED IN COMPUTING BIRTHS FOR UNITED STATES LIFE TABLES. |                                                              |                                                             |           |                                                              |                                                               |           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|-------------------------------------------------------------|-----------|--------------------------------------------------------------|---------------------------------------------------------------|-----------|

|                                                                                                                                                                                                     |                                                              | Males.                                                      | Females.  |                                                              | Males.                                                        | Females.  |
|                                                                                                                                                                                                     |                                                              | Per cent.                                                   | Per cent. |                                                              | Per cent.                                                     | Per cent. |
| 0-1                                                                                                                                                                                                 | 0                                                            | 72                                                          | 71        | 1                                                            | 28                                                            | 29        |
| 1-2                                                                                                                                                                                                 | 1                                                            | 59                                                          | 59        | 2                                                            | 41                                                            | 41        |
| 2-3                                                                                                                                                                                                 | 2                                                            | 53                                                          | 53        | 3                                                            | 47                                                            | 47        |
| 3-4                                                                                                                                                                                                 | 3                                                            | 52                                                          | 52        | 4                                                            | 48                                                            | 48        |
| 4-5                                                                                                                                                                                                 | 4                                                            | 52                                                          | 52        | 5                                                            | 48                                                            | 48        |

When these percentages are applied to the deaths in the parallelograms of Diagram 15 the result is to apportion them to their corresponding elementary triangles. For example, 28 per cent of 14,569 is 4,079 to the nearest integer, and 72 per cent of 14,569 is 10,490.

<sup>2</sup> Bureau of the Census, Bulletin 109, Mortality Statistics: 1910, pp. 154, 155.

DIAGRAM 17.—APPLICATION OF FACTORS IN TABLE 109 TO DEATHS IN DIAGRAM 15; ALSO INSERTION OF CORRESPONDING POPULATIONS FROM TAPE 139, PAGE 373.

Diagram 17 shows the new distribution: 4,079 is entered just above and 10,490 just below the horizontal line which divides the corresponding parallelogram into its two elementary triangles. A study of this diagram shows that it is possible to follow the progress of each generation. For example, of the 14,569 deaths that occurred in 1909 under 1 year, 10,490 were born in 1909; of the 15,234 deaths in 1910 under 1 year, 4,266 were born in 1909. Likewise, of the 3,401 deaths in 1910 aged 1 last birthday, 2,007 were of persons belonging to the 1909 generation; and of the 2,993 deaths in 1911 between 1 and 2 years of age, 1,227 belonged to the 1909 generation. In short, all the deaths occurring among persons born in 1909 must be in the triangles lying between the two horizontal lines inclosing the year 1909.

In order to determine the number of births in a given calendar year, it is necessary to know the number of deaths among those born in that calendar year and the number of survivors at the end of the calendar year. Accordingly, on the lower of the two diagonal lines, between which the calendar year is written, the populations on December 31 of that year are entered. The population between any two years of age, that is, in any age interval, is written on that section of the diagonal line intercepted between the two vertical lines inclosing the age interval. For example,

the population on December 31, 1909, taken from tape 139, page 373, between birth and 1 year of age is 96,835, and this number appears in Diagram 17 on the lower of the two diagonal lines between which 1909 is written and on the section inclosed by the two vertical lines at whose tops appear the ages 0 and 1, respectively. Likewise, the population on December 31, 1910, between 1 and 2 years of age, that is, in age interval 1-2, is 87,439, and this number appears in Diagram 17 on the lower of the two diagonal lines between which 1910 is written and between the two vertical lines at whose tops appear the ages 1 and 2, respectively.

Since on December 31, 1909, there were 96,835 infants under 1 year of age still alive, while 10,490 of those born in 1909 died during that year, the total number of births during 1909 should be the sum of 96,835 and 10,490, or 107,325. This determines the number of births in 1909 from the population and deaths under 1 year of age. The number of births in 1909 may also be determined from the population aged 1 to 2 years on December 31, 1910, and the deaths under 2 years of age among males who were born in 1909. Diagram 17 shows the number of births in this case to be  $87,439 + 10,490 + 4,266 + 2,007 = 104,202$ . Similarly, from the population between 2 and 3 years of age on December 31, 1911, and the deaths among

males under 3 years of age who were born in 1909, the number of male births in 1909 appears to be  $97,260 + 10,490 + 4,266 + 2,007 + 1,227 + 700 = 115,950$ . Starting with the male population in age interval 3-4 on December 31, 1912, and again with the male population in age interval 4-5 on December 31, 1913, and adding the corresponding deaths occurring in the 1909 generation, the male births in 1909 are found to be 114,389 and 111,666, respectively.

**POPULATIONS UNDER 2 YEARS NOT EMPLOYED TO CALCULATE NUMBER OF BIRTHS.**

110. Since the deaths for 1914 were not available when these calculations were made, the births for 1910 could be derived only from the populations in age intervals 0-1, 1-2, 2-3, and 3-4 years, and these births were, respectively, 109,670, 105,766, 117,869, and 115,948. Likewise, the births for 1911 could be derived only from the populations in age intervals 0-1, 1-2, and 2-3, and these births were, respectively, 110,714, 106,484, and 119,050. Table 110 sets forth the results in systematic form.

**Table 110**

| NUMBER OF MALE BIRTHS IN THE STATE OF NEW YORK IN 1909, 1910, AND 1911,<br>DERIVED FROM THE POPULATION AND MORTALITY STATISTICS. |                                                            |         |         |         |         |

A study of this table shows that the numbers of births derived from the populations aged 2-3, 3-4, and 4-5 years, respectively, are considerably higher than those derived from populations in age intervals 0-1 and 1-2, respectively. A review of the population statistics of the United States and also those of many foreign countries shows that the populations under 2 years of age are generally understated, especially the population between 1 and 2 years of age. In the Supplement to the Seventy-fifth Annual Report of the Registrar-General, Part I, Life Tables, pages 10 to 13, it is shown that in the populations enumerated in England and Wales on March 31, 1901, and on April 2, 1911, those for ages 2-3, 3-4, and 4-5 are substantially in agreement with those derived from births and deaths alone, while those for ages 0-1 and 1-2 fall far short of those derived from births and deaths alone, the conclusion being that many infants under 2 years of age are not enumerated in the census. It is not intended to discuss here the reasons for these understatements of infant populations.

Accordingly it was decided to use only the number of births derived from populations aged 2-3, 3-4, and 4-5 years in determining the number of births for

the period 1909-1911. In order to give equal weight in this determination to the populations at these three ages, the sum of the births in 1909 derived from populations aged 4-5, in 1910 derived from populations aged 3-4, and in 1911 derived from populations aged 2-3 was used as the number of births during the three-year period. Referring to Table 110, this sum is seen to be  $111,666 + 115,948 + 119,050 = 346,664$ .

For each of the three calendar years 1900, 1901, and 1902 the average number of births computed from the populations aged 2-3, 3-4, and 4-5 was taken as the number of births for the year. Then the number of births for the three calendar years was taken as the sum of these values. In the same way, for each of the calendar years in the decennium 1901 to 1910, the computed number of births was taken as the average of the three computed from the populations aged 2-3, 3-4, and 4-5, respectively. Then the sum of these averaged computed number of births for each of the ten calendar years was used in the calculation of rates of mortality for the life tables.

The same method was adopted for the two 1890 Massachusetts tables, and it was assumed that populations and deaths remained the same for the five calendar years beginning June 1, 1889. This assumption was made necessary because there were no original statistics upon which to estimate the change in the number of deaths year by year from 1889 to 1894.

For males and females, Massachusetts in 1901 and 1910, Boston in 1901 and 1910, New York City in 1910, and Philadelphia in 1910, the birth registration statistics were employed instead of computed number of births based on population and mortality statistics. In all these cases the registered and computed number of births were in close agreement. Table 136, showing the computed number of births and the number of births registered, when reported, and the difference between them, is shown on page 425.

**CALCULATION OF RATES OF MORTALITY FOR SINGLE YEARS UNDER 5 YEARS OF AGE.**

111. In determining the rates of infant mortality by months under 1 year and by single years under 5 years of age, equation (18), slightly modified for purposes of computation, was employed. When  $\xi = 1$  and  $\frac{1}{2}\delta_{x+1/z+2}^{z_1/z_2}$  is subtracted from both sides of equation (18), it becomes

$$E_{x+1}^{t_1/t_2} - \frac{1}{2}\delta_{x+1/z+2}^{z_1/z_2} = E_x^{t_1/t_2} - \frac{1}{2}\delta_{x/z+1}^{z_1/z_2} - D_{x/z+1}^{z_1/z_2} - \frac{\delta_{x/z+1}^{z_1/z_2} + \delta_{x+1/z+2}^{z_1/z_2}}{2} \quad (29)$$

The interval  $(z_1, z_2)$  is the same as that of mortality statistics upon which the life table is based. With all superscripts and the second subscripts of  $\delta$  and  $D$

dropped for brevity, and with  $x=0, 1, 2, 3$ , and  $4$ , the equations are as follows:

$$\begin{aligned} E_1 - \frac{1}{2}\delta_1 &= E_0 - \frac{1}{2}\delta_0 - D_0 - \frac{\delta_0 + \delta_1}{2} \\ E_2 - \frac{1}{2}\delta_2 &= E_1 - \frac{1}{2}\delta_1 - D_1 - \frac{\delta_1 + \delta_2}{2} \\ E_3 - \frac{1}{2}\delta_3 &= E_2 - \frac{1}{2}\delta_2 - D_2 - \frac{\delta_2 + \delta_3}{2} \\ E_4 - \frac{1}{2}\delta_4 &= E_3 - \frac{1}{2}\delta_3 - D_3 - \frac{\delta_3 + \delta_4}{2} \end{aligned} \quad (30)$$

Beginning with the known value of  $E_0$ , the number of births registered or the computed number of births, the left-hand members of (30) are readily determined, since  $\delta_0, \delta_1, \delta_2, \delta_3, \delta_4$ , and  $D_0, D_1, D_2, D_3, D_4$  are known. When these are found, equation (22) is employed to compute the rate of mortality. Table 111 exhibits the process of the calculation.

Table 111

| Age interval $x$ to $x+1$ years. | Estimated population, December 31— |         | Increase in population $\delta_x$ | $\frac{\delta_x + \delta_{x+1}}{2}$ | Deaths in the three-year period 1909-1911 $D_x$ | $E_x - \frac{1}{2}\delta_x$ | $q_x = \frac{D_x}{E_x - \frac{1}{2}\delta_x}$ |
|----------------------------------|------------------------------------|---------|-----------------------------------|-------------------------------------|-------------------------------------------------|-----------------------------|-----------------------------------------------|
|                                  | 1908                               | 1911    |                                   |                                     |                                                 |                             |                                               |
| 0-1                              | 95,004                             | 100,605 | 5,601                             | 5,250                               | 43,843                                          | 343,863                     | .127501                                       |
| 1-2                              | 84,205                             | 89,103  | 4,898                             | 5,433                               | 9,917                                           | 294,770                     | .033643                                       |
| 2-3                              | 91,293                             | 97,260  | 5,967                             | 5,338                               | 4,349                                           | 279,420                     | .015561                                       |
| 3-4                              | 88,394                             | 93,103  | 4,709                             | 4,204                               | 2,510                                           | 269,733                     | .009305                                       |
| 4-5                              | 85,046                             | 88,745  | 3,699                             | .....                               | 1,723                                           | 263,019                     | .006551                                       |

The value of  $E_0 = 346,664$ , found in the preceding section, when reduced by  $\frac{1}{2}\delta_0 = 2,801$ , gives  $343,863$  for  $E_0 - \frac{1}{2}\delta_0$ . Then  $E_1 - \frac{1}{2}\delta_1$  is determined by the first equation in (30) to be equal to  $343,863 - 43,843 - 5,250 = 294,770$ , and in a similar manner the remaining values in this column are obtained, and the numbers in the preceding column divided by the corresponding ones in this column give the mortality rates in the last column.

#### CALCULATION OF MONTHLY RATES OF MORTALITY UNDER 1 YEAR.

112. In calculating the monthly rates of mortality under 1 year the same method was employed. The census returns for June 1, 1900, and for April 15, 1910, do not show the population by months under 1 year of age. Consequently, for ages by months under 1 year, the increase in population in the three-year interval was assumed to be uniformly distributed under 1 year of age, and the monthly increase,  $\delta_x^{(12)}$ , was taken to be one-twelfth of the  $\delta_x$  previously employed for the age

interval 0-1 year. Since 5,601 is not exactly divisible by 12, the quotient being  $466\frac{9}{12}$ ,  $\delta_x^{(12)}$  for months 0, 1, 2, . . . 8 was taken as 467, while that for months 9 to 11 was taken equal to 466. Hence  $\frac{1}{2}(\delta_x^{(12)} + \delta_{x+1}^{(12)})$  equals 467 up to and including the ninth month, since  $(467+466)/2$  is set equal to 467.

The sum of the deaths for the three-year period 1909-1911 for age intervals of 1 month under 1 year of age were needed in this computation, but the original statistics in most cases were so rough that some adjustment was found necessary. This adjustment was made graphically instead of employing a mathematical formula, and in such manner that the sum of the deaths under 1 year was left unchanged. The original statistics were plotted on a large sheet, the ordinates being the number of deaths for monthly age intervals under 1 year. This work is shown in Graph 136, page 371. Beginning with the age interval 1-2 months, in which the number of deaths was left unchanged, a smooth curve was drawn in such manner with respect to the remaining ten ordinates as to leave the sum of the deaths under 1 year unchanged. Table 112 gives the original and adjusted number of deaths and indicates the process used in obtaining the monthly rates of mortality.

Table 112

| Age interval $x$ to $x+1$ months. | Increase in population $\delta_x^{(12)}$ | $\frac{\delta_x^{(12)} + \delta_{x+1}^{(12)}}{2}$ | Deaths in the three-year period 1909-1911. |                       | $E_x^{(12)} - \frac{1}{2}\delta_x^{(12)}$ | $q_x^{(12)} = \frac{D_x^{(12)}}{E_x^{(12)} - \frac{1}{2}\delta_x^{(12)}}$ |

| 9-10                              | 466                                      | 466                                               | 1,849                                      | 1,729                 | 303,363                                   | .005699                                                                   |
| 10-11                             | 466                                      | 466                                               | 1,580                                      | 1,650                 | 301,168                                   | .005479                                                                   |
| 11-12                             | 466                                      | .....                                             | 1,642                                      | 1,600                 | 299,052                                   | .005350                                                                   |

Eleven equations of the same type as (30) are now employed to determine the monthly rates of mortality, where the symbols  $E^{(12)}$ ,  $\delta^{(12)}$ , and  $D^{(12)}$  refer to months instead of to years. As before,  $E_0^{(12)} = 346,664$ , and this reduced by  $\frac{1}{2}\delta_0^{(12)} = 234$  gives the number exposed to risk,  $E_0^{(12)} - \frac{1}{2}\delta_0^{(12)} = 346,430$ . Then  $E_1^{(12)} - \frac{1}{2}\delta_1^{(12)} = 346,430 - 16,404 - 467 = 329,559$ .

Similarly,  $E_{12}^{(12)} - \frac{1}{2}\delta_{12}^{(12)} = 329,559 - 4,449 - 467 = 324,643$ , and finally,  $E_{11}^{(12)} - \frac{1}{2}\delta_{11}^{(12)} = 301,168 - 1,650 - 466 = 299,052$ . Monthly rates of mortality are then obtained by means of equation (22). It will be seen that this rate is about 47.35 per 1,000 for the first monthly age interval, 0-1, and that it reduces to 5.35 per 1,000 for the last or twelfth monthly age interval, 11-12. It is evident that if the original unadjusted rates of mortality had been used in this computation the rate would have been rough and uneven and the rate for the twelfth month would have been higher than that for the eleventh month. It is on this account that the observed deaths were first adjusted by a graphical process.

#### DERIVATION OF THE OSCULATORY FIFTH DIFFERENCE FORMULA.<sup>1</sup>

113. In determining the rates of mortality for single years of age from 4 years to about 100 years, the populations and deaths in each of the single years of age were first obtained by application of the fifth difference osculatory interpolation formula to the populations and deaths summed in quinquennial age groups. From these interpolated and graduated populations and deaths for single ages the rates of mortality were computed by equation (24).

One of the chief difficulties met with in adjusting rough data by the usual interpolation formulas is that at points where the interpolation curves meet there are sudden breaks in the values of the first differences. Various methods have been employed to effect a smooth junction or welding of these interpolation curves. The osculatory method of interpolation is based on certain fundamental assumptions which necessarily assure a smooth junction. The idea is to join two successive interpolation curves so that for a certain abscissa they shall have a common ordinate, tangent, and radius of curvature. This is accomplished by making their first and second derivatives equal, respectively, at the point of intersection deter-

mined by the abscissa and common ordinate. Since the chief part of the life table construction has been based on this method, the derivation of the fifth difference osculatory formula is given here.

It is proposed to determine an osculatory interpolation curve of the fifth degree of the form

$$y_x = (1 - c_x)u_x + c_x v_x, \quad (31)$$

where  $c_x$  is a rational algebraic function of  $x$ , and  $u_x$  and  $v_x$  are defined as follows:

$$u_x = u_{-2+(x+2)} = u_{-2} + \frac{x+2}{1}\Delta u_{-2} + \frac{(x+2)(x+1)}{2}\Delta^2 u_{-2} + \frac{(x+2)(x+1)x}{3}\Delta^3 u_{-2} + \frac{(x+2)(x+1)x(x-1)}{4}\Delta^4 u_{-2}, \quad (32)$$

and

$$v_x = v_{-1+(x+1)} = u_{-1} + \frac{x+1}{1}\Delta u_{-1} + \frac{(x+1)x}{2}\Delta^2 u_{-1} + \frac{(x+1)x(x-1)}{3}\Delta^3 u_{-1} + \frac{(x+1)x(x-1)(x-2)}{4}\Delta^4 u_{-1}. \quad (33)$$

Since  $u_{-1} = u_{-2} + \Delta u_{-2}$  and  $\Delta^s u_{-1} = \Delta^s u_{-2} + \Delta^{s+1} u_{-2}$ , it follows readily that

$$v_x = u_x + \frac{(x+1)x(x-1)(x-2)}{4}\Delta^5 u_{-2}. \quad (34)$$

Referring to equations (32) and (33) and to Diagram (18), it appears that  $u_x$  and  $v_x$  are rational integral functions of  $x$  of the fourth degree, passing through the ends of the first and last five, respectively, of the six ordinates  $u_{-2}, u_{-1}, u_0, u_1, u_2$ , and  $u_3$ . These two curves, therefore, intersect in the four points  $(-1, u_{-1})$ ,  $(0, u_0)$ ,  $(1, u_1)$ , and  $(2, u_2)$ . Since by equation (31) the curve  $y_x$  passes through any point common to  $u_x$  and  $v_x$ , it must also pass through the above four points.

Let

$$y_x = u_x + \psi_x, \quad (35)$$

where  $\psi_x$  is a rational integral function of  $x$  of the fifth degree. Then at the origin,  $x=0$ , assume that  $y_x$  and  $u_x$ , together with their first and second derivatives, are equal, respectively, and also at the point  $x=1$  that  $y_x$  and  $v_x$ , together with their first and second derivatives, are equal, respectively. Accordingly,

$$y_0 = u_0, \quad y'_0 = u'_0, \quad y''_0 = u''_0 \quad (36)$$

and

$$y_1 = v_1, \quad y'_1 = v'_1, \quad y''_1 = v''_1. \quad (37)$$

The relations (35) and (36) show that  $\psi_0 = \psi'_0 = \psi''_0 = 0$ . Hence  $\psi_x$  contains the factor  $x^3$ , while equations (34), (35), and the first one in (37) show that  $\psi_1 = 0$ , so that  $\psi_x$  contains the factor  $x-1$ .

DIAGRAM 18.—ILLUSTRATING PROOF OF FORMULA FOR OSCULATORY INTERPOLATION.

From equations (34) and (35)

$$\begin{aligned} y_x - v_x &= \psi_x - \frac{(x+1)x(x-1)(x-2)}{4} \Delta^5 u_{-2} \\ &= \psi_x - (x^4 - 2x^3 - x^2 + 2x) \frac{\Delta^5 u_{-2}}{4}, \end{aligned}$$

and since by (37),  $y_1' - v_1' = 0$  and  $y_1'' - v_1'' = 0$ ,

$$\psi_1' = (4x^3 - 6x^2 - 2x + 2)_{x=1} \frac{\Delta^5 u_{-2}}{4} = -\frac{2\Delta^5 u_{-2}}{4},$$

$$\psi_1'' = (12x^2 - 12x - 2)_{x=1} \frac{\Delta^5 u_{-2}}{4} = -\frac{2\Delta^5 u_{-2}}{4},$$

it follows, if

$$\psi_x = x^3(x-1)(a_0x + a_1) \frac{\Delta^5 u_{-2}}{4},$$

that

$$a_0 + a_1 = -2 \text{ and } 4a_0 + 3a_1 = -1.$$

Hence

$$\psi_x = x^3(x-1)(5x-7) \frac{\Delta^5 u_{-2}}{4},$$

and the required osculatory interpolation curve of the fifth degree is

$$\begin{aligned} y_x &= u_{-2} + \frac{x+2}{1} \Delta u_{-2} + \frac{(x+2)(x+1)}{2} \Delta^2 u_{-2} \\ &+ \frac{(x+2)(x+1)x}{3} \Delta^3 u_{-2} + \frac{(x+2)(x+1)x(x-1)}{4} \Delta^4 u_{-2} \\ &+ \frac{x^3(x-1)(5x-7)}{4} \Delta^5 u_{-2}. \end{aligned} \quad (38)$$

An examination of the steps in the derivation of the osculatory fifth difference formula shows that when the original statistical ordinates are given,  $u_{-2}$ ,  $u_{-1}$ ,  $u_0$ ,  $u_1$ ,  $u_2$ ,  $u_3$ ,  $u_4$ , . . .  $u_t$ , successive groups of

five, beginning with  $u_{-2}$ , determine a corresponding succession of curves  $u_x$ ,  $v_x$ ,  $w_x$ , and so on, which in turn are employed to fix the values of the tangent and the radius of curvature at certain points on the fifth difference osculatory curve  $y_x$ . Moreover, since  $v_x$ , for example, is employed with  $u_x$  to define these values at the point  $(1, u_1)$  on the osculatory fifth difference interpolation curve  $y_x$  for the interval  $(0, 1)$  and with  $w_x$  to define these values at the point  $(1, u_1)$  on the osculatory fifth difference interpolation curve  $y_x$  for the next interval  $(1, 2)$ , it follows that these two  $y_x$  curves will have a smooth junction at  $(1, u_1)$  because they have a common ordinate,  $u_1$ , a common tangent, same as  $v_x$ , and a common radius, same as  $v_x$ , at this point.

In order to adapt the notation to this succession of  $y_x$  curves, the equation (38) is written in the following form:

$$\begin{aligned} y_z &= y_{n+z+2} = y_n + \frac{x+2}{1} \Delta y_n + \frac{(x+2)(x+1)}{2} \Delta^2 y_n \\ &+ \frac{(x+2)(x+1)x}{3} \Delta^3 y_n + \frac{(x+2)(x+1)x(x-1)}{4} \Delta^4 y_n \\ &+ \frac{x^3(x-1)(5x-7)}{4} \Delta^5 y_n, \end{aligned} \quad (39)$$

where  $z = n + 2 + x$  and the symbol  $n$  denotes any integral number, including 0, and  $x$  any fraction less than unity. This is the osculatory formula for writing the values of the function for fractional values of  $z$ , which lie between the integral values  $n + 2$  and  $n + 3$ , in terms of  $y_n$  and its five leading integral differences. Five years is taken as the unit of time, and the values of  $T_x$  and  $l_x$  at ages 4, 9, 14 . . . years are used as the known values of the function at the integral values of time between which four values of the function are to be interpolated at the fractional values of time .2, .4, .6, and .8, or, in other words,  $T_x$  and  $l_x$  for the four single years within each quinquennial group, such as 4-8, 9-13, and so on.

#### LEADING FRACTIONAL DIFFERENCES IN TERMS OF LEADING INTEGRAL DIFFERENCES.

114. To obtain the equations for the function at these four fractional values of  $z$ , these values, .2, .4, .6, and .8, are substituted for  $x$  in equation (39). These four equations, together with the two equations for the boundary values,  $x = 0$  and  $x = 1$ , when differenced five times, give five leading fractional differences of  $y_n$  in terms of its leading integral differences, and the results are set forth in Table 113.

Table 113

| DERIVATION OF LEADING FRACTIONAL DIFFERENCES IN TERMS OF LEADING INTEGRAL DIFFERENCES. |       |              |                |                |                |                |         |

In this table  $y_n$  and each of its first five leading integral differences head columns in which are written the corresponding coefficients in the equations for the fractional differences appearing on the left. For example,

$$\delta^2 y_{n+2.4} = .04\Delta^2 y_n + .064\Delta^3 y_n + .0160\Delta^4 y_n - .0080\Delta^5 y_n.$$

Table 113 shows that the leading fractional differences of  $y_{n+2}$  can be expressed in terms of the leading unit differences of  $y_n$ . These equations are so important that they are brought together for reference.

Equations (40)

| $\delta^5 y_{n+1}$ | - |              |                |                |                | + .0080        |

They are frequently employed in connection with life tables to calculate the leading single year differences in terms of the leading quinquennial differences of an age ten years younger. If third difference formulas are employed, as in the case of the construction of the recent English Life Tables,<sup>1</sup> the leading single

<sup>1</sup> Supplement to the Seventy-fifth Annual Report of the Registrar-General of England and Wales, Part I, Life Tables, pp. 50-52.

year differences are given in terms of the leading quinquennial differences of an age five years younger. These formulas require the calculation of the leading differences for every fifth year for the entire range of the table considered. The question arises as to whether the proper correction to the fifth difference, where fifth difference formulas are employed, can not be found so as to make the process of calculation continuous without computing the leading differences for every quinquennial set. The fifth difference correction can be determined in the following manner.

#### DETERMINATION OF THE FIFTH DIFFERENCE CORRECTION.

115. In Table 113 only one fifth fractional difference appears, namely,  $\delta^5 y_{n+2} = .0080\Delta^5 y_n$ . Evidently then, equations of the function for values of  $z$  between  $n+3$  and  $n+4$  are necessary to obtain the formulas for the fifth fractional differences of the function for other values of  $z$  between  $n+2$  and  $n+3$ . In other words, the values  $\delta^5 y_{n+2.2}$ ,  $\delta^5 y_{n+2.4}$ ,  $\delta^5 y_{n+2.6}$ ,  $\delta^5 y_{n+2.8}$ , and  $\delta^5 y_{n+3}$  are required, in addition to the above value of  $\delta^5 y_{n+2}$  given in Table 113. Employing equation (39) with  $z = n+3+x = (n+1)+x+2$ , a table precisely similar to Table 113 can be constructed, except that  $n$  is replaced throughout by  $n+1$ . The numerical coefficients in this table would be the same as those in Table 113, the effect being merely to deal with the next unit interval to the right. However, since  $y_{n+1} = y_n + \Delta y_n$ , any equation in terms of  $y_{n+1}$  and its five leading integral differences can readily be transformed into an equation in terms of  $y_n$  and its six leading integral differences. For example, since

$$y_{n+1} = y_n + \Delta y_n, \quad \Delta y_{n+1} = \Delta y_n + \Delta^2 y_n,$$

$$\Delta^2 y_{n+1} = \Delta^2 y_n + \Delta^3 y_n, \quad \Delta^3 y_{n+1} = \Delta^3 y_n + \Delta^4 y_n,$$

$$\Delta^4 y_{n+1} = \Delta^4 y_n + \Delta^5 y_n, \quad \Delta^5 y_{n+1} = \Delta^5 y_n + \Delta^6 y_n,$$

it appears that, when the  $y_{n+2}$  to  $y_{n+3}$  interpolations are expressed in terms of  $y_n$  and its leading differences, the coefficient of  $y_n$  will be unchanged, the coefficient of  $\Delta y_n$  will be algebraically increased by that of  $y_n$ , the coefficient of  $\Delta^2 y_n$  will be algebraically increased by that of  $\Delta y_n$ , of  $\Delta^3 y_n$  by that of  $\Delta^2 y_n$ , of  $\Delta^4 y_n$  by that of  $\Delta^3 y_n$ , of  $\Delta^5 y_n$  by that of  $\Delta^4 y_n$ , and finally  $\Delta^6 y_n$  will have the same coefficient as  $\Delta^5 y_n$  in Table 113.

As an example, by Table 113,

$$\delta^4 y_{n+3} = +.0016\Delta^4 y_{n+1} - .0032\Delta^5 y_{n+1}.$$

When  $y_n + \Delta y_n$  is substituted for  $y_{n+1}$ , this equation becomes

$$\delta^4 y_{n+3} = (.0016\Delta^4 y_n + .0016\Delta^5 y_n)$$

$$- (.0032\Delta^5 y_n + .0032\Delta^6 y_n)$$

$$= +.0016\Delta^4 y_n - .0016\Delta^5 y_n - .0032\Delta^6 y_n.$$

Hence it appears that any coefficient of  $\Delta^p y_n$  in an equation for  $\delta^q y_{n+3}$  may be obtained by adding to the coefficient of  $\Delta^p y_n$  in the equation for  $\delta^q y_{n+2}$  the co-

efficient of  $\Delta^{p-1}y_n$  immediately preceding it. By this process the equations (40) lead to the equations (41).

Equations (41)

|                    |   | $\Delta y_n$ | $\Delta^2 y_n$ | $\Delta^3 y_n$ | $\Delta^4 y_n$ | $\Delta^5 y_n$ | $\Delta^6 y_n$ |
|--------------------|---|--------------|----------------|----------------|----------------|----------------|----------------|
| $\delta y_{n+2}$   | = | + .2         | + .52          | + .408         | + .0704        | -.0160         | +.0016         |
| $\delta^2 y_{n+2}$ | = |              | + .04          | + .088         | + .0496        | + .0064        | +.0048         |
| $\delta^3 y_{n+2}$ | = |              |                | + .008         | + .0144        | + .0016        | -.0048         |
| $\delta^4 y_{n+2}$ | = |              |                |                | + .0016        | -.0016         | -.0032         |
| $\delta^5 y_{n+2}$ | = |              |                |                |                | + .0080        | + .0080        |

With these equations and others taken from Table 113 the differencing necessary to obtain the formulas for the fifth fractional differences of the function for values of  $x$  between  $n+2$  and  $n+3$  can be continued. In the scheme of differencing shown below the equations are grouped according to the order of differences. In each group the first equation is taken from Table 113 and the last equation from the equations (41). The intermediate equations, inclosed in braces, are derived by differencing those in the groups just above.

Since  $\Delta^6 y_n = \Delta^5 y_{n+1} - \Delta^5 y_n$ , these fifth fractional differences may all be written in terms of the fifth integral differences of  $y_n$  and  $y_{n+1}$ . In these transformed equations it is evident that the coefficients of  $\Delta^5 y_{n+1}$  are the same as those of  $\Delta^6 y_n$  in the original equations and that any coefficient of  $\Delta^5 y_n$  in a transformed equation may be obtained by subtracting the coefficient of  $\Delta^6 y_n$  algebraically from that of  $\Delta^5 y_n$  in the

corresponding original equation. Therefore, the fractional differences may be expressed as shown in Table 115.

Table 115

| δ⁵y <sub>n+3</sub>                                                                                                                               | = | .0000            | +.0080             | = | 0                                                 | +5 |

It will be noticed that all the coefficients are multiples of  $+.0016$ . As the actual computation is materially shortened by working with  $+.0016\Delta^2 y_n$  instead of with just  $\Delta^2 y_n$ , the transformation of these equations, shown at the right in Table 115, was made.

FOURTH DIFFERENCE INTERPOLATION CURVES EMPLOYED AT BEGINNING AND END OF FIFTH DIFFERENCE OSCULATORY INTERPOLATION.

116. It appears from equations (32) and (38) or (39) that when  $\Delta^5 y_{-2} = 0$  the osculatory fifth difference interpolation curve  $y_x = u_x + \psi_x$  reduces to  $y_x = u_x$ . Therefore, if it is desired to start the interpolation from  $y_0$  with a fourth difference equation  $y_x = u_x$  for the first two quinquennial age groups, the method in Table 115 will apply if  $\Delta^5 y_{-10}$  and  $\Delta^5 y_{-5}$  are taken equal to zero. This will make the corrected unit fifth differences

$$\delta^5 y_0 = \delta^5 y_1 = \delta^5 y_2 = \delta^5 y_3 = \delta^5 y_4 = 0,$$

and since  $y_0$  is given and its leading unit differences can be directly calculated in terms of the leading quinquennial differences of  $y_0$  by the equations (42), it follows that the first ten interpolated values  $u_0, u_1, \dots, u_9$  are derived by continuous addition.

Equations (42)

|                | $\Delta y_0$ | $\Delta^2 y_0$ | $\Delta^3 y_0$ | $\Delta^4 y_0$ |
|----------------|--------------|----------------|----------------|----------------|
| $\delta y_0$   | = +.2        | -.08           | +.048          | -.0336         |
| $\delta^2 y_0$ | =            | +.04           | -.032          | +.0256         |
| $\delta^3 y_0$ | =            |                | +.008          | -.0096         |
| $\delta^4 y_0$ | =            |                |                | +.0016         |

The next pair of quinquennial fifth differences,  $\Delta^5 y_{-5} = 0$  and  $\Delta^5 y_0$ , furnish the next five values of the corrected unit fifth differences, and these in turn lead to the next five interpolated values,  $u_{10}, u_{11}, u_{12}, u_{13}, u_{14}$ , on the first osculatory fifth difference interpolation curve. It should be carefully noted that by the process of continuous addition any five successive unit fifth differences lead to five values of the function at the next five higher ages. The steps are illustrated in Table 116.

Table 116

JUNCTION OF FOURTH DIFFERENCE INTERPOLATION CURVES WITH FIFTH DIFFERENCE INTERPOLATION CURVES AT BEGINNING AND END OF RANGE OF INTERPOLATION.

| FOURTH DIFFERENCE INTERPOLATION CURVE<br>$y_x=u_x$ | FIFTH DIFFERENCE INTERPOLATION CURVE<br>$y_x=u_x+\psi_x$ | FOURTH DIFFERENCE INTERPOLATION CURVE<br>$y_x=u_x$ |

|                                                                                                                                                                                                                                                                       | 4                                                                                                                        | 1                   | 3                  | 9     | 1                  | 3               | 14  | 1               | 3               | 19  | 1               | 3                  | 24  | 1                  | 3                  | 29  | 1                  | 3                  |

An examination of this table shows how the unit fifth differences are obtained and the corresponding range of the interpolated unit ordinates. The table illustrates an interpolation running from  $y_0$  to  $y_{34}$ . The fourth difference interpolation curve  $y_x = u_x$  is employed in the first two quinquennial groups, followed by three successive fifth difference osculatory curves of the type  $y_x = u_x + \psi_x$ , covering the next three quinquennial age groups, and finally a fourth difference curve of type  $y_x = u_x$  furnishing the interpolations for the last two quinquennial age groups. It will be observed that  $\Delta^5 y_{15}$  and  $\Delta^5 y_{20}$  are taken equal to zero, so that the corrected fifth differences for the last ten years, 20 to 29, lead to the values of ordinates on a fourth difference curve in the range 25 to 34. To summarize, the interpolations are by a fourth difference curve in range 0 to 9, by three fifth difference osculatory curves in range 10 to 24, and by a fourth difference curve in range 25 to 34. The curves of type  $y_x = u_x$  necessarily make a smooth junction with the first and last osculatory curves because by equations (36) and (37) they have a common ordinate, tangent, and radius of curvature, respectively, at the junction ( $10, u_{10}$ ) and ( $25, u_{25}$ ). The application of this theory is shown in the description of the calculation of the life table for males in the state of New York, 1910, section 158 on pages 378 to 386.

**WITTSTEIN'S FORMULA MODIFIED FOR THE RATES OF MORTALITY AT ADVANCED AGES.**

117. Where the census returns and mortality statistics furnished populations and deaths by single years of age to the end of life, it was possible to extend the calculation of the rates of mortality to ages 100 and over. These statistics were available for more than half the life tables shown in this volume, but for thirty-two life tables the populations and deaths were

available only in the quinquennial age groups 0-4, 5-9, and so on, up to 90-94, 95 and over, or 95-99, 100 and over. For these thirty-two tables the calculation of rates of mortality could not be extended satisfactorily beyond ages 94 or 99 by the usual interpolation methods. Moreover, in all the life tables the rates of mortality for ages beyond 80 became irregular, sometimes even decreasing with increasing age. Accordingly, some method had to be devised to determine the rates from about age 80 to the end of life so that they would form a smooth table and at the same time keep as close as possible to the original data.

Obviously the only recourse was to make some assumption as to the rates of mortality near the end of life so that from this assumption and rates of mortality at older ages already determined it would be possible to calculate the rates of mortality up to some limiting age. After many preliminary experiments with various formulas, it was decided to employ Wittstein's formula, namely,

$$q_x = a^{-\frac{(x-x)^n}{m}} + \frac{1}{m} a^{-(m-x)^n}.$$

Since the value of the last term of this equation is practically zero at the older ages, only the first term of the second member of the equation was employed. In this formula,  $M$  was taken equal to 115 where  $q_{115} = 1$ , making  $\omega = 116$ , the limiting age. This left  $a$  and  $n$  as the constants to be determined in the equation

$$q_x = a^{-\frac{(x-x)^n}{m}}. \quad (43)$$

The details of this calculation are described in section 119.

After the rates of mortality had been calculated according to equation (43) they were joined to the main table of rates by the smoothing process described in section 121.

OLD AGE RATES EMPLOYED TO DETERMINE CONSTANTS.

118. It is shown in section 119 that the constants  $a$  and  $n$  in equation (43) are based upon ten or more rates of mortality at older ages which have already been determined. From experiments made in determining rates from the five possible quinquennial groups it was found that the accumulated deviations of the expected deaths from the actual were smallest when the rates were made to depend upon a combination of all the groups. Hence, where the population and deaths by single years were available the rates from which the above constants were determined were made to depend upon all the groups. In the case of the thirty-two tables mentioned above, where only one group is available, more than ten rates were used in the determination of the constants when this was necessary.

The formula used to graduate the population and death statistics by all the different groups is the one for obtaining the graduated value of the central term of a series of fifteen values of a function. It was employed by Mr. George King to obtain graduated quinquennial pivotal values and is derived by him as follows:<sup>1</sup>

Let there be a series of fifteen values of  $u$ , the function to be dealt with, from  $u_0$  to  $u_{14}$ . To find the graduated value of  $u_7$ , the central term of the series.

Let  $y$  be the finite integral of the function  $u$ , so that  $y_x = \sum_0^{x-1} u$ ; and let  $\Delta y$ ,  $\Delta^2 y$ , etc., be the differences of  $y$  for quinquennial intervals, so that  $\Delta y_0 = \sum_0^4 u$ ,  $\Delta y_5 = \sum_5^9 u$ , and so on. Then

$$\begin{aligned} u_7 &= y_8 - y_7, \\ y_8 &= y_0 + \frac{8}{5}\Delta y_0 + \frac{24}{50}\Delta^2 y_0 - \frac{8}{125}\Delta^3 y_0, \\ y_7 &= y_0 + \frac{7}{5}\Delta y_0 + \frac{14}{50}\Delta^2 y_0 - \frac{7}{125}\Delta^3 y_0; \end{aligned}$$

hence

$$\begin{aligned} u_7 &= \frac{1}{5}\Delta y_0 + \frac{1}{5}\Delta^2 y_0 - \frac{1}{125}\Delta^3 y_0 \\ &= .2\Delta y_5 - .008\Delta^3 y_0. \end{aligned}$$

The differences,  $\Delta$ , of  $y$  are the sums of five values of the function  $u$ , and may be represented by the symbol  $w$ , so that

$$w_x = u_x + u_{x+1} + u_{x+2} + u_{x+3} + u_{x+4}. \quad (44)$$

Accordingly,

$$u_7 = .2w_8 - .008\Delta^2 w_0. \quad (45)$$

When

$$w_x = L_x + L_{x+1} + L_{x+2} + L_{x+3} + L_{x+4} = -\Delta T_x,$$

then

$$L_{x+2} = .2w_x - .008\Delta^2 w_{x-5}, \quad (46)$$

<sup>1</sup> Supplement to the Seventy-fifth Annual Report of the Registrar-General of England and Wales, Part I, Life Tables, Appendix II, sec. 2, p. 49.

and when

$$w_x = d_x + d_{x+1} + d_{x+2} + d_{x+3} + d_{x+4} = -\Delta L_x,$$

then

$$d_{x+2} = .2w_x - .008\Delta^2 w_{x-5} \quad (47)$$

The populations and deaths from about age 80 to the end of life were summed in each of the five possible quinquennial groups and equations (46) and (47), respectively, applied to the original data summed in each group. The graduated populations and deaths thus obtained were from all the different groups, only populations and deaths five years apart being from the same groups. After the rates of mortality had been computed they were summed in fives, and the average of each sum was taken as the value for the central age in that sum. Thus these mean rates of mortality are based upon original data grouped in each of the five possible quinquennial groups.

DETERMINATION OF CONSTANTS IN WITTSTEIN'S FORMULA.

119. The constants employed to determine the rates of mortality for older ages through age 114 were the arithmetic means,  $\bar{n}$  and  $\log \log a$ , of five sets of values for  $n$  and  $\log \log a$ , which were derived from the rates of mortality for ten consecutive ages, as follows:

- the first set from  $q_x$  and  $q_{x+5}$ ,
- the second set from  $q_{x+1}$  and  $q_{x+6}$ ,
- the third set from  $q_{x+2}$  and  $q_{x+7}$ ,
- the fourth set from  $q_{x+3}$  and  $q_{x+8}$ ,
- the fifth set from  $q_{x+4}$  and  $q_{x+9}$ .

The method of selecting the ten consecutive rates of mortality upon which are based  $\bar{n}$  and  $\log \log a$  is shown in section 188, page 392, for life table for males in the state of New York, 1910.

In order to obtain any one of the sets of values, equation (43) was written in the logarithmic form

$$\log q_x = -(M-x)^n \log a$$

and two equations formed by substituting for  $x$  the two ages  $b$  and  $b+5$ . Accordingly,

$$\log q_b = -(M-b)^n \log a$$

and

$$\log q_{b+5} = -(M-b-5)^n \log a;$$

from which

$$\frac{\log q_b}{\log q_{b+5}} = \frac{(M-b)^n}{(M-b-5)^n};$$

whence,

$$n = \frac{\log(-\log q_b) - \log(-\log q_{b+5})}{\log(M-b) - \log(M-b-5)}. \quad (48)$$

After  $n$  was determined the value of  $a$  was derived from the equations

$$\log \log a = \log(-\log q_b) - n \log(M-b)$$

$$\log \log a = \log(-\log q_{b+5}) - n \log(M-b-5). \quad (49)$$

## THE OVERLAPPING SERIES OF RATES OF MORTALITY.

120. For the older ages there are now three sets of overlapping rates of mortality, namely, those near the end of the table determined by the osculatory process, those determined by the group process described in section 118, and those determined by Wittstein's formula. The first two sets are based upon the original population and death data but derived by different methods, and the third is based upon the second set and upon an hypothesis as to the variation of the rates of mortality as the age approaches the limit of life. These three sets of rates of mortality for males in the state of New York, 1910, are shown in tape 205, page 397. The method of selecting a fourth set of rates of mortality from these three which will be fairly representative of all three, and yet be less irregular than any one of them, is set forth in section 205, page 396.

For the thirty-two tables mentioned in section 117 there were only two overlapping sets of rates of mortality at the older ages, but the derivation of a third set from these two was made in the same way.

SPENCER'S 21-TERM FORMULA.<sup>1</sup>

121. A number of smoothing processes were tried upon this fourth set of rates of mortality, and finally it was decided to use the results obtained by the application of Spencer's 21-term formula, that is, where  $\bar{u}$  represents the smoothed central value and  $u$  the unsmoothed values,

$$\bar{u}_0 = [5]^2[7]\{-u_{-3} + u_{-1} + 2u_0 + u_1 - u_3\}/350. \quad (50)$$

This formula is based upon the assumption that the smoothed values shall have a constant third difference. Since the operand requires seven terms, that is, six more than the central term, while adding twice in fives and once in sevens requires fifteen more terms, twenty-one terms in all are required to give one smoothed central term. Hence the table of smoothed values will begin at an age 10 years older than the unsmoothed one.

## SUMMARY OF METHODS EMPLOYED TO OBTAIN THE RATES OF MORTALITY.

122. To summarize, the rates of mortality upon which any life table was based were obtained in the following manner:

1. Monthly rates of mortality under 1 year, when the statistics were available, and annual rates of mortality by single years of age under 5 were computed from mortality statistics and from the number exposed to risk of death determined from births, deaths, and increase in population according to census returns. The deaths by months under 1 year were adjusted

by a graphical process explained in section 136, page 370.

2. When the rates under 5 years of age, worked according to the process described in paragraph 1 of this section, did not form a smooth junction with rates for ages following 5, worked according to the method described in paragraph 3, a special process was applied to from six to fourteen rates beginning with age 3 to produce a smooth junction. The rates thus obtained, beginning with age 4, were used for the life table. This process is described in sections 250 to 263, pages 408 to 410.
3. Annual rates of mortality from the last age computed according to paragraph 2 up to the old ages were obtained from graduated interpolated values of populations and deaths by single ages, obtained by the application of the fifth difference osculatory formula to population and death statistics summed in the quinquennial age groups 4-8, 9-13, or 5-9, 10-14, and so on.
4. Annual rates of mortality from about age 80 to some age near 100 were obtained by the application of Spencer's 21-term formula to a set of rates of mortality selected from the following sources:
  - (a) Rates described in paragraph 3.
  - (b) Rates, each of which was the arithmetic mean of five consecutive rates of mortality, obtained from populations and deaths derived by the application of the formula
 
$$u_{x+7} = .2 \sum_{x=5}^{x=9} u_x - .008\Delta^2 \sum_{x=0}^{x=4} u_x$$
 to population and death statistics summed in each of the five quinquennial groups, respectively.
  - (c) Rates described in paragraph 5.

For the thirty-two tables mentioned in section 117, only (a) and (c) were available.
5. Annual rates of mortality from some age near 100 through age 115 were obtained by the application of Wittstein's formula for old ages to the rates of mortality obtained as described in paragraph 4 (b).

## CALCULATION OF THE DERIVED MORTALITY FUNCTIONS.

123. The rates of mortality were obtained from the statistical data by methods already described. The derived columns,

$$l_x, d_x, \bar{e}_x, L_x, L_x/d_x, T_x, 1000l_x/T_x,$$

appearing in each life table were then calculated from these rates of mortality with the further assumption of a stationary population supported by  $l_0$  persons born alive uniformly throughout each year.

<sup>1</sup>On the Graduation of the Rates of Sickness and Mortality presented by the Experience of the Manchester Unity of Odd-fellows during the period 1893-1897. John Spencer. Journal of the Institute of Actuaries, vol. 38, p. 334.

This population was also assumed to be unaffected by emigration and immigration. Under these conditions the formulas derived in this text, establishing relations between the various aggregates of the living and dead, are considerably simplified. For example, all generations are alike, the populations for each age interval remain constant, and the elementary areas  $abdf$ , Diagram 12, page 336, together with their corresponding elementary triangles  $abd$ ,  $dfa$ , respectively, are unchanged from generation to generation. In other words, for all values of  $t$

$$E_x^{t/t+1} = l_x, \quad P_{x+1}^{x/t+1} = L_x, \quad \text{and} \quad D_{x/t+1}^{t/t+1} = d_x.$$

Equation (14) becomes

$$\frac{E_{x+1}^{t/t+1}}{E_x^{t/t+1}} = \frac{l_{x+1}}{l_x} = p_x \quad \text{and} \quad l_{x+1} = p_x l_x. \quad (51)$$

Accordingly, when the radix of the table,  $l_0$ , was taken as 100,000, the number of survivors at each age was obtained by multiplying the products of the  $p_x$  up to that age by 100,000. These products were copied to the nearest fourth decimal place, and the multiplications were performed upon a ten-place computing machine. The  $d_x$  were obtained by differencing the  $l_x$ .

#### CALCULATION OF THE DERIVED MORTALITY FUNCTIONS UNDER 5 YEARS.

124. It is also evident that

$$D_\delta = D_\beta = k (D_\alpha + D_\beta) = k D_{x/t+1}^{t/t+1} = k d_x,$$

where  $k$  is the percentage of deaths in  $D_\beta$  to the total deaths,  $d_x$ , in  $abdf$ . Hence, by section 104,

$$L_x = l_{x+1} + D_\beta = l_{x+1} + k d_x,$$

and with the percentages shown in Table 109, page 340, the formulas for ages 1, 2, 3, and 4 become

$$\begin{aligned} L_1 &= l_2 + .41d_1 = (41l_1 + 59l_2)/100, \\ L_2 &= l_3 + .47d_2 = (47l_2 + 53l_3)/100, \\ L_3 &= l_4 + .48d_3 = (48l_3 + 52l_4)/100, \\ L_4 &= l_5 + .48d_4 = (48l_4 + 52l_5)/100. \end{aligned} \quad (52)$$

Beyond age 4 it is assumed that  $D_\alpha = D_\beta$ ; in other words,  $k = .50$ . Hence for such values of  $x$

$$L_x = l_{x+1} + .50d_x = (l_x + l_{x+1})/2. \quad (53)$$

For the age interval 0-1 the formula for males was

$$L_0 = l_1 + .28d_0$$

and for females

$$L_0 = l_1 + .29d_0,$$

except in those cases where there was an infant mortality table, when  $L_0$  for the yearly age interval 0-1 was necessarily taken as the sum of the popula-

tions for the twelve monthly age intervals under 1 year.

For ages under 1 year, where the values are given by months, the formula employed for the first month is

$$L_0^{(12)} = (l_1^{(12)} + .25d_0^{(12)})/12 = (l_0^{(12)} + 3l_1^{(12)})/48, \quad (54)$$

the superscript  $(12)$  referring to the monthly values. This result is based on the assumption that when the plane is divided up into monthly instead of annual elementary parallelograms and triangles, as in Diagram 12, page 336,

$$D_\delta^{(12)} = .25D_{0/1}^{t/t+1}.$$

In other words, the deaths in the first month of life during any month of time are divided between the earlier and later monthly generations in the ratio of 1 to 3. In the publication of the Bureau of the Census, Bulletin 109, Mortality Statistics, 1910, Table 10, pages 154 to 191, there are given for the calendar year 1910 the number of deaths by days for the first week of life and by weeks for the remaining three weeks of the first month of life. By employing the theory developed in section 108, in connection with formulas (25) and (26), it was possible to calculate for various areas the ratio of the number of deaths  $D_\delta^{(12)}$  in the upper elementary monthly triangle to the number of deaths in the parallelogram  $D_{0/1}^{t/t+1}$ . For example, the deaths in the original registration states gave the ratio as .2400; Massachusetts, .2378; New York, .2531; and New York City, .2747. This led to the adoption of  $k = .25$  for the first month of life. The following table exhibits the calculation of  $k$  for the state of New York.

Table 117

| DETERMINATION OF PERCENTAGE OF DEATHS UNDER 1 MONTH TO BE ADDED TO THOSE SURVIVING TO AGE 1 MONTH TO OBTAIN POPULATION UNDER 1 MONTH. |         |                   |           |
|---------------------------------------------------------------------------------------------------------------------------------------|---------|-------------------|-----------|
| Age interval.                                                                                                                         | Factor. | Number of deaths. | (2) X (3) |
| (1)                                                                                                                                   | (2)     | (3)               | (4)       |
| <i>In days</i>                                                                                                                        |         |                   |           |
| 0-1                                                                                                                                   | 1       | 2,395             | 2,395     |
| 1-2                                                                                                                                   | 3       | 1,474             | 4,422     |
| 2-3                                                                                                                                   | 5       | 714               | 3,570     |
| 3-4                                                                                                                                   | 7       | 532               | 3,724     |
| 4-5                                                                                                                                   | 9       | 397               | 3,573     |
| 5-6                                                                                                                                   | 11      | 336               | 3,696     |
| 6-7                                                                                                                                   | 13      | 232               | 3,016     |
| Total .....                                                                                                                           |         |                   | 21,396    |
| 24,396 + 730 .....                                                                                                                    |         |                   | 33.42     |
| <i>In weeks.</i>                                                                                                                      |         |                   |           |
| 1-2                                                                                                                                   | 3       | 1,352             | 4,146     |
| 2-3                                                                                                                                   | 5       | 1,244             | 6,220     |
| 3-4                                                                                                                                   | 7       | 1,094             | 7,658     |
| Total .....                                                                                                                           |         | 9,690             | 18,024    |
| 18,024 + 104 .....                                                                                                                    |         |                   | 173.31    |
| Ratio = $\frac{33.42 + 173.31}{9,000/12} = .2531$                                                                                     |         |                   |           |

As there were no statistics upon which to base the value of this ratio for the remaining months under 1 year of age,  $k$  was taken as .50, leading to the equation

$$L_x^{(m)} = (l_{x+1}^{(m)} + .50d_x^{(m)})/12 = (l_x^{(m)} + l_{x+1}^{(m)})/24. \quad (55)$$

To obtain the population aged  $x$  and over,  $T_x$ , the following equation was used:

$$T_x = \sum_{i=x}^{\sigma} L_i, \quad (56)$$

where  $\sigma$  represents the last age in the life table.

The expectation of life was derived according to the equation

$$\bar{e}_x = T_x/L_x, \quad (57)$$

while the measure of vitality or population per death was obtained from the equations

$$\lambda_x^{(m)} = 12L_x^{(m)}/d_x^{(m)} \quad \text{and} \quad \lambda_x = L_x/d_x, \quad (58)$$

for values under 1 year the ratio,  $L_x^{(m)}/d_x^{(m)}$ , being multiplied by 12. The values of both  $\bar{e}_x$  and  $\lambda_x$  were determined to the nearest second decimal place from the integral values of  $T_x$  and  $L_x$ ,  $L_x$  and  $d_x$ , respectively, up to age 80. From age 80 to the end of life they were determined from the values of  $T_x$  and  $L_x$ ,  $L_x$  and  $d_x$ , respectively, taken to the nearest fourth decimal place.

The average death rate per thousand of the population aged  $x$  and over was computed to the nearest second decimal place by the equation

$$1000/\bar{e}_x = 1000L_x/T_x. \quad (59)$$

#### SPECIAL FORMULAS AND PROCESSES.

125. The theory of life table construction developed in the text up to this point embodies chiefly methods and processes which were quite generally employed on all the life tables, and, in particular, in the calculation of the life table for males in the state of New York, 1910. The details of the arithmetic processes in computing this table are fully explained on pages 370 to 408. For example, the method of obtaining the rates of mortality for single years of age under 5, the osculatory fifth difference interpolation formula, and Wittstein's old-age formula are employed in calculations for every life table. In some cases, however, special methods had to be devised to secure satisfactory results, and these will now be described.

#### JUNCTION OF RATES OF MORTALITY UNDER AGE 5 WITH RATES BY OSCULATORY INTERPOLATION.

126. The rates of mortality, ages 0 to 4 years, obtained by the method described in section 111 from populations calculated from births and deaths, and those for ages 4 and over, obtained from populations and deaths graduated by the fifth difference osculatory formula, do not always form a smooth junction. In these cases the rates of mortality were regraduated near the age at which the two sets of tables were

joined. The smoothing process selected for this purpose is based on a modification of Lagrange's theorem, namely,

$$m_x = \frac{(x-b)(x-c)}{(a-b)(a-c)}m_a + \frac{(x-c)(x-a)}{(b-c)(b-a)}m_b + \frac{(x-a)(x-b)}{(c-a)(c-b)}m_c + (x-a)(x-b)(x-c)K, \quad (60)$$

where  $m_x$  is the central death rate and  $a$ ,  $b$ , and  $c$  are the abscissas of rates of mortality already determined.

In order to shorten the work, equation (60) was transformed by moving the origin a distance  $a$  to the right so that the new age variable is  $y = x - a$  and the abscissas of the three known rates of mortality are 0,  $e = b - a$ ,  $f = c - a$ , respectively. When the products of the constants in each of the first three terms in the right-hand member of equation (60) are denoted by  $U_a$ ,  $U_b$ , and  $U_c$ , respectively, this equation becomes

$$m_x = (y-e)(y-f)U_a + (y-f)yU_b + y(y-e)U_c + Ky(y-e)(y-f).$$

Whence, expanding,

$$m_x = (U_a + U_b + U_c)y^2 - [(e+f)U_a + fU_b + eU_c]y + efU_a + K[y^3 - (e+f)y^2 + efy], \quad (61)$$

or,

$$m_x = Uy^2 - Vy + efU_a + K[y^3 - (e+f)y^2 + efy], \quad (62)$$

where the constants for which  $U$  and  $V$  are substituted are obvious.

In order to determine the value of  $K$  the condition was made that the sum of the expected deaths for the ages under consideration must equal the sum of the actual deaths at these ages; that is,

$$\sum L_x m_x = M, \quad (63)$$

where  $M$  is the sum of the actual deaths at the ages under consideration. Substituting in equation (63) the value of  $m_x$  in equation (62) and solving for  $K$ , the following equation is obtained:

$$K = \frac{M - U \sum y^2 L_x + V \sum y L_x - ef U_a \sum L_x}{\sum y^3 L_x - (e+f) \sum y^2 L_x + ef \sum y L_x}. \quad (64)$$

Table 118 furnishes a convenient outline to calculate the values of  $U$  and  $V$ .

In applying the above formulas to join the two sets of tables of rates of mortality,  $a$  was always taken as the age immediately preceding the  $n$  ages whose rates of mortality were to be determined, while  $b$  and  $c$  immediately follow these  $n$  ages. To determine the products of the powers of  $y$  by  $L_x$ , a second table was formed.

Table 119

| SECOND OUTLINE USED IN CALCULATION OF RATES OF MORTALITY JOINING THOSE UNDER AGE 5 WITH THOSE BY OSCULATORY INTERPOLATION. |         |           |           |              |               |                 |                 |

| $a+2$                                                                                                                      | 2       | 4         | 8         |              |               |                 |                 |
| $a+3$                                                                                                                      | 3       | 9         | 27        |              |               |                 |                 |
| etc.                                                                                                                       | etc.    | etc.      | etc.      |              |               |                 |                 |
| $a+n-1$                                                                                                                    | $n-1$   | $(n-1)^2$ | $(n-1)^3$ |              |               |                 |                 |
| $a+n$                                                                                                                      | $n$     | $n^2$     | $n^3$     |              |               |                 |                 |
| $b$                                                                                                                        | $b-a=c$ | $c^2$     | $c^3$     |              |               |                 |                 |
| $c$                                                                                                                        | $c-a=f$ | $f^2$     | $f^3$     |              |               |                 |                 |
| Totals.....                                                                                                                |         |           |           | $\Sigma L_x$ | $\Sigma yL_x$ | $\Sigma y^2L_x$ | $\Sigma y^3L_x$ |

After the determination of  $K$  the first and second differences of  $m_a$  and the constant third difference were computed, and the values of  $m_x$  from  $a+1$  to  $c$  were obtained by continuous addition, the check on the work being, of course, that the values for  $m_b$  and  $m_c$  obtained by this process were the same as those in the first table. To obtain the equations for the three leading differences of  $m_a$ , equation (62) was differenced three times. Since the values of  $y$  are the natural numbers and when  $x=a$ ,  $y=0$ , the first difference of all three powers of  $y$  is one, the second difference of  $y^2$  is two, and the second and third differences of  $y^3$  are each six when  $x=a$ . Hence

$$\begin{aligned}\delta m_a &= U - V + K[1 - (e+f) + ef] \\ \delta^2 m_a &= 2U + K[6 - 2(e+f)] \\ \delta^3 m_a &= 6K.\end{aligned}\quad (65)$$

When several tables are to be computed, having the same ages for  $a$ ,  $b$ , and  $c$ , the first four columns in the second table and the coefficients of  $K$  in equation (65) need be computed only once. An example of an application of this method to the life table for white females in cities of the original registration states, 1901, appears in sections 250 to 263, pages 408 and 410, and in the corresponding tapes, page 409.

#### DETERMINATION OF MEAN POPULATION.

127. In order to compare the rates of mortality in this country with those in others where life tables had been constructed from statistics covering the ten-year period 1901-1910, similar tables were pre-

pared for white males and white females in the original registration states. These two life tables are based on the census enumerations of June 1, 1900, and April 15, 1910, and the reported deaths for the ten calendar years 1901 to 1910, shown in Tables 173 and 174 on pages 464 and 465. The details of this work are explained in sections 264 to 274 on pages 410, 413, and 414 and in the corresponding tapes on pages 411 and 412.

The formula<sup>1</sup> used in determining the mean population for the ten-year period 1901-1910 is a modification of those employed for the English Life Tables.<sup>2</sup> The assumption is made that the population as a whole increases by geometrical progression, so that, if  $e$  be the time between the taking of two censuses in which the total populations were  $P_0$  and  $P_e$ , respectively, then

$$P_e = r^{e/u} P_0, \quad (66)$$

where  $u$  is the unit of time on which the constant  $r$  is based. Also after any time interval  $t$  the entire population is

$$P_t = r^{t/u} P_0. \quad (67)$$

When the total population has been determined in this way it is assumed that any subdivision of the population at the time  $t$  is

$$\pi_t = m\pi_0 + n\pi_e, \quad (68)$$

where  $\pi_0$  and  $\pi_e$  are the populations of these same subdivisions at the first and second censuses, respectively. If  $m+n=1$ , it follows that when  $\pi_0=\pi_e$ , then  $\pi_t=\pi_0$ ; also, since the total population is equal to the sum of the subdivisions, that

$$\Sigma \pi_t = m\Sigma \pi_0 + (1-m)\Sigma \pi_e = P_t = mP_0 + (1-m)P_e. \quad (69)$$

Accordingly,

$$m = \frac{P_e - P_t}{P_e - P_0}, \quad \text{and} \quad 1-m = \frac{P_t - P_0}{P_e - P_0}. \quad (70)$$

Substituting in equations (70) the values of  $P_e$  and  $P_t$  from equations (66) and (67), respectively, they become

$$m = \frac{r^{e/u} - r^{t/u}}{r^{e/u} - 1} \quad \text{and} \quad 1-m = \frac{r^{t/u} - 1}{r^{e/u} - 1}. \quad (71)$$

If  $\Delta = \pi_e - \pi_0$ , then  $\pi_e = \pi_0 + \Delta$ . Substituting this value for  $\pi_e$  in equation (68), this equation becomes

$$\pi_t = m\pi_0 + (1-m)(\pi_0 + \Delta) = \pi_0 + (1-m)\Delta, \quad (72)$$

and substituting the expression for  $1-m$  in equation (71) for  $1-m$  in equation (72), this equation becomes

$$\pi_t = \pi_0 + \frac{r^{t/u} - 1}{r^{e/u} - 1} \Delta. \quad (73)$$

<sup>1</sup> Note upon Estimates of Population. Alfred C. Waters. Seventieth Annual Report of the Registrar-General, 1907, p. cxxxii.

<sup>2</sup> Supplement to the Seventy-fifth Annual Report of the Registrar-General of England and Wales, Part 1, Life Tables, p. 47.

Then the mean population over a period  $l$ , which begins an interval  $h$  after the taking of the first census, is the integral of  $\pi_t dt$ , between the limits of time  $t=h$  and  $t=h+l$ , divided by the length of the period. In other words, if  $\bar{\pi}_l$  be the mean population over the period  $l$  in any subdivision, then

$$\begin{aligned}\bar{\pi}_l &= \frac{1}{l} \int_h^{h+l} \pi_t dt = \frac{1}{l} \int_h^{h+l} \left[ \pi_0 + \frac{(r^{t/u} - 1)}{(r^{l/u} - 1)} \Delta \right] dt \\ &= \frac{1}{l} \left[ l\pi_0 + \left\{ \frac{u(r^{(h+l)/u} - r^{h/u})}{\lambda r} - l \right\} \frac{\Delta}{r^{l/u} - 1} \right] \\ &= \pi_0 + \left\{ \frac{u}{l} \cdot \frac{r^{h/u}(r^{l/u} - 1)}{\lambda r} - 1 \right\} \frac{\Delta}{r^{l/u} - 1}, \quad (74)\end{aligned}$$

where  $\lambda r$  denotes the Napierian logarithm of  $r$ .

The total mean population for the period  $l$  is

$$\bar{P}_l = \frac{1}{l} \int_h^{h+l} P_t dt = \frac{P_0}{l} \int_h^{h+l} r^{t/u} dt = \frac{u P_0}{l} \cdot \frac{r^{h/u}(r^{l/u} - 1)}{\lambda r}. \quad (75)$$

The results obtained from equation (74) for the different subdivisions,  $\bar{\pi}_l$ , are checked when their sum equals the value for  $\bar{P}_l$  obtained from equation (75).

In this case the first census was taken on June 1, 1900, and the second on April 15, 1910, so that the time between the taking of the two censuses was  $e=118.5$  months. The period of time for which the mean population was desired was from December 31, 1900, to December 31, 1910, or  $l=10$  years = 120 months, and  $h=7$  months. The unit of time on which the ratio  $r$  was based is  $l$ , or  $u=l=120$  months. Hence, equation (74) may be written

$$\bar{\pi}_l = \pi_0 + \left\{ \frac{r^{7/120}(r-1)}{\lambda r} - 1 \right\} \frac{\Delta}{r^{118.5/120} - 1} = \pi_0 + \beta \Delta, \quad (76)$$

and equation (75) becomes

$$\bar{P}_l = \frac{P_0}{\lambda r} r^{7/120}(r-1) = \alpha P_0. \quad (77)$$

This formula was also employed to determine the mean population for the following four tables for the ten-year period 1901-1910: Negro males and Negro females in the original registration states and in the District of Columbia. The original statistics from which these life tables were constructed appear in Tables 175 to 178, pages 466 to 469.

RATES OF MORTALITY CALCULATED FOR LIFE TABLES TESTED FOR SMOOTHNESS AND CONFORMITY TO ORIGINAL STATISTICS.

128. It is the practice of actuaries and statisticians to test the goodness of graduation by an examination of the third differences. This test requires that the differences be small and that they oscillate frequently and regularly from positive to negative and negative to positive. This means that the absolute sum of the differences and accumulated or net differences must be small. Table 120 shows such a test of the rates of mortality upon which were based the life tables for white males and for white females in the original registration states in 1910. The totals for this table include the sum of the positive differences, the sum of the negative differences, and the accumulated or algebraic sum of the positive and negative differences, denoted as *net*, and the sum of the positive and negative differences irrespective of signs, denoted as *absolute*. Totals are given for all ages and also for those with ages 0-1 and 1-2 excluded. It will be observed that after age 2 the differences are small and frequently change signs. This is verified by the totals for white males, net, -106, and absolute, 1,878; for white females, net, +34, and absolute, 2,060. The third differences are also shown for the infant mortality section of the tables.

It is not to be expected that the differences will be small for the first two or three years of life because it is well known that the rate of mortality at these ages does not even approximate a third degree curve.

| Males.                 |  |  |  |  |                       |  |  |  |  |                       |  |  |  |  |                       |  |  |  |  |                       |  |  |  |  |          |  |  |  |  |

In Table 124, page 359, in column headed group 4-8, a similar test is given for the rates of mortality between ages 15 and 85 upon which the life table for males in the state of New York, 1910, was based. These rates of mortality were derived from population and death statistics graduated by the application of the fifth difference osculatory formula to the original statistics summed in the 4-8 group.

A very satisfactory test of the success of the graduated rates of mortality is to apply them to the original population statistics to determine the expected number of deaths and compare these with the actual number of deaths as recorded in the mortality statistics. If the deviations of the expected deaths from the actual deaths are small, both as to net and absolute totals, where the population is large, the life table may be regarded as faithfully representing mortality conditions in the original population. In Table 121 this test is applied to measure the deviations of expected from actual deaths in the large populations

for white males and white females in the original registration states in 1910. Each of these populations numbers over eleven and one-half millions, and during the three-year period 1909-1911 there were 567,661 deaths among males and 496,378 deaths among females. The expected number of deaths among males by the life table rates of mortality is 556,913, or about 98 per cent of the actual number; the expected number of deaths among females is 487,895, also about 98 per cent of the actual number of deaths. If the first two age intervals, namely, 0-1 and 1-2, are excluded, the expected number of deaths in both cases is less than two-tenths of 1 per cent of the actual. To put it in another way, the total number of deaths of white males over age 2 in the three-year period 1909-1911 was 434,594, while the expected number which would be predicted by making use of the table is 434,216, a difference of 378, or less than one-tenth of 1 per cent, in about 400,000 deaths. Among females in the same period the actual number of deaths was

389,206, the expected number by the table, 388,630, a difference of only 576, or less than two-tenths of 1 per cent.

The expected deaths in Table 121 are shown for five-year groups after the first four age intervals. They were calculated by applying the reciprocal of the

measure of vitality,  $1/\lambda_x$ , to three times the estimated population on July 1, 1910.

This test is also applied in Table 125, page 360, to the graduations by the different quinquennial age groups for males in the state of New York in 1910, and with very satisfactory results.

TABLE 121.—DEVIATIONS OF EXPECTED DEATHS FROM ACTUAL DEATHS AMONG WHITES IN THE ORIGINAL REGISTRATION STATES, 1910.

| AGE INTERVAL.                                 | MALES.                             |                          |         |                                            | FEMALES.                           |                          |         |                                            |
|-----------------------------------------------|------------------------------------|--------------------------|---------|--------------------------------------------|------------------------------------|--------------------------|---------|--------------------------------------------|
|                                               | Estimated population July 1, 1910. | Deaths during 1909-1911. |         | Deviations of expected from actual deaths. | Estimated population July 1, 1910. | Deaths during 1909-1911. |         | Deviations of expected from actual deaths. |
|                                               |                                    | Expected.                | Actual. |                                            |                                    | Expected.                | Actual. |                                            |
| 0-1                                           | 254,307                            | 103,237                  | 111,131 | + 7,894                                    | 247,817                            | 81,878                   | 87,613  | + 5,735                                    |
| 1-2                                           | 226,129                            | 19,460                   | 21,936  | + 2,476                                    | 220,930                            | 17,387                   | 19,559  | + 2,172                                    |

VARIATION OF RATES OF MORTALITY WITH QUINQUENNIAL AGE GROUPS OF STATISTICS TO WHICH THE OSCULATORY INTERPOLATION FORMULA IS APPLIED.

129. An examination of the original statistics shows that there is a bunching of figures for populations and deaths at ages which are multiples of 2 and 5, especially pronounced at ages ending in the digits 0, 5, and 8. On this account the selection of the quinquennial age groups becomes important, because this selec-

tion determines the location within these groups of the ages ending in 0, 5, and 8. Designating each of the five possible quinquennial age groups by the ages in its first group, these are group 0-4, group 1-5, group 2-6, group 3-7, and group 4-8, respectively. When statistics are summed according to the group 3-7, the central age of each sum ends in 0 or 5. Group 3-7 is the central one of the five possible groups in the tables which follow. These tables begin with group 1-5

and end with group 0-4 (or 5-9, as it is designated when it follows group 4-8). The male population in the state of New York, estimated as of July 1, 1910, and the deaths for the three-year period 1909-1911 from Table 159, page 450, were each added in each of the five quinquennial age groups and graduated by application of the fifth difference osculatory interpolation formula to each of these groups. The rates of mortality, ages 15 to 85, from each of these five sets of graduated population and mortality statistics and also those from the average of these five sets of graduated

populations and mortality statistics, or *average group*, are shown in Table 122. The rates of mortality in this average group are in fact the rates which would be obtained by applying King's 29-term osculatory interpolation formula<sup>1</sup> to the original statistics. The rates of mortality in the second column of Table 122 are from the ungraduated population and mortality statistics and are designated the *observed rates*,  $o_{1x}$ .

<sup>1</sup> Notes on Summation Formulas of Graduation with Certain New Formulas for Consideration. George King. Journal of the Institute of Actuaries, vol. 41, p. 543.

TABLE 122.—VARIOUS RATES OF MORTALITY OBTAINED FROM SAME ORIGINAL STATISTICS.

Statistics used were populations estimated as of July 1, 1910, and reported deaths for 1909, 1910, and 1911 of males in the state of New York. See Table 159, p. 450.

*Observed rates of mortality from ungraduated population and mortality statistics,  $o_{1x}$ .*

*Rates of mortality from population and mortality statistics graduated by applying fifth difference osculatory interpolation formula to original statistics grouped in each of the five quinquennial age groups.*

*Rates of mortality from the average of these five sets of graduated population and mortality statistics, *average group*.\**

\* Average values of population and mortality statistics graduated from all five quinquennial age groups could also be obtained by the 29-term osculatory interpolation formula. See Notes on Summation Formulas of Graduation. George King. Journal of the Institute of Actuaries, vol. 41, p. 543.

Table 123 shows the excess of  $10^6 q_x$  for the groups 1-5, 2-6, 3-7, 4-8, and 5-9, respectively, over the average group in Table 122, that is, the deviations for each group from their mean or average values. It will be observed that the totals are given for each of the five different groups for the age intervals 15-85 and

28-77. The age interval 28-77 was chosen because the decided exaggeration of populations and deaths for ages ending in 0, 5, and 8 apparently lies within these limits. The totals in Table 123 show that the groups 2-6, 3-7, and 4-8 bear this test well, and the absolute totals, 21,417 and 8,574, quite definitely favor the group 4-8.

TABLE 123.—DEVIATIONS OF RATES OF MORTALITY FOR EACH GROUP FROM THOSE FOR THE AVERAGE GROUP IN TABLE 122, MULTIPLIED BY  $10^6$ .

| AGE. | AGE GROUP OF POPULATION AND MORTALITY STATISTICS TO WHICH OSCULATORY INTERPOLATION FORMULA WAS APPLIED. |     |     |     |     |     |     |     |     |     | AGE.                                   | AGE GROUP OF POPULATION AND MORTALITY STATISTICS TO WHICH OSCULATORY INTERPOLATION FORMULA WAS APPLIED. |         |        |         |         |     |       |     |       |       |

| 59   |                                                                                                         | 406 |     | 345 | 325 |     | 178 |     | 242 |     |                                        |                                                                                                         |         |        |         |         |     |       |     |       |       |

In Table 124 the groups are considered from another angle, namely,  $10^5$  times the third differences of the rates of mortality in Table 122 for each age and the various totals of the same. While the indications here are not decisive, it is noted that the sums of the absolute values, 1,073 for age interval 15-85 and 479 for age interval 28-77, show that the smallest differences are in the 4-8 group. The net differences in the two

age intervals, however, -143 and 137, respectively, are larger than in most of the other groups.

Papps<sup>1</sup> has discussed the methods employed in Tables 123 and 124, and from results he obtained in age intervals 30-37 and 30-40, respectively, declares in favor of group 3-7.

<sup>1</sup> Effect of Grouping in Graduation by Osculatory Interpolation. P. C. H. Papps. Quarterly Publication of the American Statistical Association, vol. 16, p. 190.

TABLE 124.—THIRD DIFFERENCES OF GRADUATED RATES OF MORTALITY IN TABLE 122.

$$10^5 \delta^3 q_x.$$

Rates were taken to nearest fifth decimal place and multiplied by 10.

Another method which may help to decide upon the age group is to find the deviation of the expected deaths from the actual deaths by means of the mortality rates shown in Table 122. The expected deaths were obtained by multiplying three times the estimated population at each age as of July 1, 1910, by the cor-

responding central death rate, the multiplier 3 being used because the deaths are for the three-year period 1909-1911. The results are exhibited in Table 125, and indicate that the choice must lie in the groups 2-6, 3-7, and 4-8, but do not show clearly which of these should be selected.

## UNITED STATES LIFE TABLES.

Another criterion which should be given careful consideration is that which requires the sum of the weighted squared deviations of the graduated values from the observed values to be a minimum. Although there are systematic errors, as opposed to accidental errors, in the population and mortality statistics, it is also true that they compensate in a remarkable degree in the calculation of certain mortality functions. The systematic exaggerations in population returns are almost paralleled in the mortality statistics for even ages and ages which are multiples of 5, and a graph of the observed rate of mortality,  ${}_oq_x$ , shows that the systematic errors are almost eliminated.

It may therefore be assumed that the weight of the squared deviation  $(q_x - {}_oq_x)^2$  is approximately equal to  $w_x = n/p_x q_x$ , where  $n$ , the number of observations, may be taken equal to the graduated population,  $P_x$ , to avoid the systematic errors in the enumerated population. For the object in hand only relative weights, or proportional populations, are required, and by employing the formula

$$\frac{P_x}{p_x q_x} (q_x - {}_oq_x)^2$$

a test is obtained on the hypothesis that systematic errors have been removed from the enumerated population and the observed rate of mortality.

TABLE 126.—WEIGHTED SQUARED DEVIATIONS OF GRADUATED RATES OF MORTALITY FROM OBSERVED RATES OF MORTALITY IN TABLE 122.

$$\frac{10^3 P_x}{p_x q_x} (q_x - {}_oq_x)^2$$

| 54   | 1,530                                                                                                   | 476   | 20     | 19     | 298    | 30             |                                     |                                                                                                         |         |         |         |         |                |

This formula has been applied to the five quinquennial groups and the average group in Table 122, and the results are set forth in Table 126. The test indicates that the minimum sum of weighted squared deviations of the rate of mortality is associated with the 2-6 group and that the sum is even lower than that for the average group, which is next in order. Among the quinquennial groups the next in order for both the age intervals 15-85 and 28-77 is the 4-8 group. The showing is least favorable for the 3-7 group, which has multiples of 5 in the center. The group usually employed in presenting vital and population statistics, namely, the 5-9 group, also shows to disadvantage under this test.

#### RATIO TEST FOR CONCENTRATION IN AGE GROUPS.

130. Another very different method<sup>1</sup> of considering this problem is to examine the ratio of the number in any quinquennial age group to the number which is the mean of the two adjoining quinquennial age groups. If the populations or deaths were not artificially exaggerated at certain ages, this ratio should vary with the age with a certain degree of regularity; if it does not, the group which shows the smallest average difference between these ratios for groups

<sup>1</sup> The Comparative Accuracy of Different Forms of Quinquennial Age Groups. Allyn A. Young. Quarterly Publication of the American Statistical Association, vol. 7, p. 27.

including ages ending in 0 and ending in 5 may be regarded as approaching more nearly the group in the actual undisturbed population and death groups.

In Table 127 populations summed in all five quinquennial age groups are arranged so that sums including populations for the same age ending in 0 or ending in 5 are in the same line with that age, which is shown under the heading "Age common to all five groups,  $x$ ." Thus the sums in the first line are made up of populations aged 11 to 19 and each contains the population aged 15, group 1-5 containing population aged 11 to 15, group 2-6 containing population aged 12 to 16, and so on to group 5-9 containing population aged 15 to 19. In the second line the population ranges from 16 to 24 years of age, and the population aged 20 is included in each of the five sums.

Then the ratio of the number in each quinquennial age group including an age ending in 0 to the sum of those immediately above and below it, each containing an age ending in 5, is designated by  ${}_0M_x$ , while the ratio of the number in each age group including an age ending in 5 to the sum of those immediately above and below it, each including an age ending in 0, is designated by  ${}_5M_x$ , the  $x$  designating the age in the numerator. The ratios are calculated for ages 20 to 95 for population of males in the state of New York, estimated as of July 1, 1910.

TABLE 127.—QUINQUENNIAL AGE GROUPS TESTED BY COMPARING RATIOS OF POPULATION.

Ratio of number in age group including age ending in 0 to sum of those immediately above and below it, each including an age ending in 5, is designated by  ${}_0M_x$ .  
Ratio of number in age group including age ending in 5 to sum of those immediately above and below it, each including an age ending in 0, designated by  ${}_5M_x$ .  
Population of males in the state of New York, estimated as of July 1, 1910.

\* Original registration states include Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Indiana, Michigan, and the District of Columbia.

Table 128 shows the  ${}_0M_x$  and  ${}_5M_x$  in Table 127 between ages 20 and 80 entered in separate columns; the average,  ${}_0\bar{M}_t$  and  ${}_5\bar{M}_t$ , of the values in each column, where  $t$  denotes age intervals 20-65, 25-80, and 30-75 years; the differences of the averages,

$$\begin{aligned} &{}_0\bar{M}_{20-65} - {}_5\bar{M}_{20-65}, \\ &{}_0\bar{M}_{25-80} - {}_5\bar{M}_{25-80}, \\ &\text{and } {}_0\bar{M}_{30-75} - {}_5\bar{M}_{30-75}; \end{aligned}$$

and the average of these averages for populations, estimated as of July 1, 1910, of males in the state of New York, of males and of females in the original registration states, and for deaths during the period 1909-1911 among these three populations.

This method favors the groups 2-6, 4-8, and 5-9.

**SELECTION OF QUINQUENNIAL AGE GROUP FOR OSCULATORY INTERPOLATION IN CONSTRUCTION OF UNITED STATES LIFE TABLES.**

131. King<sup>1</sup> made an exhaustive study of quinquennial age groups and concluded that the 4-8 group would furnish graduated populations most faithfully reflecting the true distributions of populations with respect to age, and he based his construction of the English Life Tables No. 8 on the 4-8 group.

Taking into account the preceding results and references, it is not difficult to eliminate groups 1-5 and 5-9. However, the decision as to groups 2-6, 3-7, and 4-8 still remains a problem. As between these three groups it will be observed that groups 2-6 and 3-7 contain both the ages ending in the digits 0 and 8 in the same quinquennial age group, while the adjacent five-year groups contain the ages ending in the digit 5. This tends to exaggerate unduly alternate quinquennial age groups in these sets. With the group 4-8, however, the ages ending in the digits 5 and 8 are in the same quinquennial group and the ages ending in the digit 0 are in the adjacent five-year groups. Since the exaggeration for ages which are multiples of 10 is undoubtedly greater than for ages which end in the digit 5, the group 4-8 would seem to furnish a better balanced grouping than the group 2-6 or 3-7.

In the construction of the United States Life Tables the 4-8 group was employed where populations and deaths by single years were available; otherwise the 5-9 group was employed, since it was the only one available.

**GRAPHS FOR AGE INTERVAL UNDER 1 YEAR AND AGE INTERVAL UNDER 1 MONTH.**

132. When the figures in the several columns of the life tables are plotted for monthly intervals under 1 year and for annual intervals beginning with age 1, it is only necessary in most cases to connect the points by drawing a smooth curve through them to obtain the required graph. There are some exceptions

to this rule, notably for the number of survivors and for monthly rates of mortality for days and weeks of age under 1 month and the annual rates of mortality for each month of age under 1 year. The variation is so great in these intervals that unless the points are simply connected by a straight line some approximate method must be devised to draw the curves. In the case of Diagram D in the graphs of expectation of life and measure of vitality straight lines were drawn in the first monthly interval, but for Diagram D in the graphs of number of survivors and monthly rate of mortality the straight line in the first month was replaced in each case by a curve, and for Diagram A in the annual rate of mortality the straight line for the first year was also replaced by a curve.

To this end it was necessary to determine a few points on these curves by computing approximate monthly rates of mortality beginning with the first few days of life and each of the first few weeks of life and also the approximate annual rates of mortality by months under 1 year of age. The mortality statistics given in Table 129 were employed, after being adjusted graphically so as to leave the total number of deaths unchanged.

<sup>1</sup> Report on the Graduation of Ages. George King. Census of England and Wales. 1911, vol. 7, p. xxxix.

The number of deaths under 1 month as given in the life table was divided approximately into deaths during each of the first three days of life and during each of the first four weeks of life by assuming that they were proportional to the number of adjusted deaths in Table 129 for the same age intervals. In order to obtain the number of deaths for corresponding intervals during the second month of life, the number of deaths during the second month of life, as given by the life table, was divided by 4 to obtain the average number per week, and then this quotient was divided by 7 to determine the average number per day. Where the quotients were not whole numbers the remainders were taken up by increasing the deaths during each of the earlier periods by unity. From these values it was possible to obtain the approximate number of deaths during each of the months beginning with each of the first three days of life and with each of the first four weeks of life, respectively, and also to find the approximate number of survivors to each of these age intervals. From these numbers of deaths and survivors

approximate monthly rates of mortality were computed.

The adjusted numbers of deaths by months in the second year of life given in Table 129 were used to divide by proportion the deaths during the second year of life, as given by the life table, into deaths by months. From these numbers of deaths during each month in the second year of life and from the deaths by months under 1 year of age, as given by the life table, the approximate numbers of deaths were obtained for the years beginning with each month under 1 year of age, and these were employed, together with the table of survivors given in the life table, to compute the approximate annual rates of mortality for each month under 1 year of age.

The adjusted deaths for Boston, Chicago, New York City, and Philadelphia during the first three days, and the first four weeks of life in 1910 and 1911, were used in a similar manner in drawing the graphs for whites in cities of the original registration states in 1901 and 1910.

## PART VII

DESCRIPTION OF CALCULATION OF LIFE TABLE FOR MALES IN THE STATE  
OF NEW YORK, 1910, INCLUDING PHOTOGRAPHS OF GRAPHS, DIAGRAMS,  
AND ADDING-MACHINE TAPES USED IN CONNECTION WITH NUMERICAL  
COMPUTATIONS.

TABULAR OUTLINE FOR CONSTRUCTION OF EACH LIFE TABLE.

## PART VII.—DESCRIPTION OF CALCULATION OF LIFE TABLE FOR MALES IN THE STATE OF NEW YORK, 1910, INCLUDING PHOTOGRAPHS OF GRAPHS, DIAGRAMS, AND ADDING-MACHINE TAPES USED IN CONNECTION WITH NUMERICAL COMPUTATIONS.

### DESCRIPTIVE TEXT AND PHOTOGRAPHED TAPES.

133. The object of this part of the text is to give a detailed account of the actual processes of calculation used in the construction of a typical life table. There are many students and others interested in vital statistics who do not understand the mathematical theory and formulas developed in Part VI who would like to know how a life table is calculated. It is quite possible to present the work of calculation in such manner that one need not necessarily be an actuary to follow the steps. The method of procedure in this part is to divide the work into a number of distinct steps and to describe each one of these steps in detail in the text. The actual process of carrying out the work on the adding machine or otherwise is shown by means of photographs of graphs, diagrams, and adding-machine tapes used in connection with the numerical calculations. The number of the section in the text in which the process is described is assigned to the corresponding tape which appears in the photograph. These numbers are shown above and to the left of the tapes, graphs, or diagrams to which they are assigned in such large heavy figures that they can be readily detected. For example, 220, above and to the left of a tape on page 403, means that the description of this tape will be found in section 220, page 402. On the other hand, the text leads to the correct tape in the photograph by direct reference. For example, if the numerical process exhibited on tape 150 is referred to in the text, it is understood that the reader will turn to this particular tape, which can be found easily by its number. The pages of photographs contain a graph and several diagrams used in the process of constructing life tables; they are numbered consecutively with the tapes. For the convenience of the reader the description of these calculations is so distributed that the photographs of the tapes generally face the page on which their descriptions appear. The process of copying values, either from the tapes or from computing machines, in Table 56 on page 162, of course, has no tape, graph, or diagram connected with it. Sections 237-239 and 244-249 describe this work. See page 10 of the table of contents.

Numerous devices and short cuts to facilitate the work on the adding machine are explained in the text and illustrated on the tapes.

Particular attention is called to the methods of checking the work. The checks are designated by

small circles inclosing the same number and placed beside the results which check each other.

### SPECIAL METHODS USED IN CONSTRUCTION OF SOME LIFE TABLES.

134. It is shown in Part VIII that the original statistics upon which life tables are based are far from uniform—in fact, that they are presented in seven different types or forms. This means that it was not possible to apply one and the same process to construct every life table. In order to meet variations from the standard or typical form of construction illustrated by the life table for males in the state of New York, 1910, and described in this part, it was necessary to devise other methods. Where these methods are not obvious they have been described in this part, the description following that of the construction of the above-mentioned table.

For example, where the infant mortality curve did not join smoothly with the osculatory fifth difference curve it was necessary to effect a smooth junction, and the process used, as illustrated in the table for white females in cities of the original registration states, 1901, is described in this part.

The same remark applies to the junction of the osculatory fifth difference curve with the Wittstein old-age curve in the table for males in the state of New York, 1910.

In the calculation of the mean population for the 1901-1910 tables it was also necessary to employ methods not used in the other tables. The method of calculating the mean population is illustrated in this part by reproducing the work on the life table for white females in the original registration states, 1901-1910.

### EXTRA INFORMATION NEEDED FOR CONSTRUCTION OF EACH LIFE TABLE.

135. As stated above, on account of the variety of forms in which the original statistics are given, it was not possible to employ the same methods in computing the rates of mortality for every table. To supply the actuary with all the information necessary to reproduce the rates of mortality for any of the life tables, a tabular outline was prepared, showing for each table the different processes used and the ages and sources of the population or death statistics or rates of mortality to which these processes were applied. This outline, Table 135, is given on pages 416 to 419.

The C's in column 3 indicate that the *computed* number of births was used instead of the number of births *registered*, R. Column 4 shows the quinquennial age groups of the original data to which the osculatory formula was applied. Beginning with column 5, the words *original statistics* and the tape numbers corresponding to sections in the description of the calculation of various parts of the life table are given at the heads of the columns. These headings indicate the *sources* of the population or death statistics or rates of mortality for the *ages* named in the table, which are used for the purpose named in the main heading of the group of columns. Thus, whenever the smoothing process described in sections 250 to 263 was employed to effect smooth junctions at early ages, columns 5 to 10 show the ages and sources of the population, death statistics, and the rates of mortality to which this process was applied; columns 12 and 13 show the ages and sources of the rates of mortality upon which the Wittstein constants were based; columns 14 to 16 show the ages and sources of rates of mortality which were smoothed by Spencer's 21-term formula; and finally, columns 17 to 22 show the ages and sources of the rates of mortality upon which the life table was constructed.

#### ADJUSTMENT FOR DEATHS BY MONTHS UNDER 1 YEAR OF AGE.

136. When the reported deaths by months under 1 year of age are plotted as shown in the broken curve marked REPORTED DEATHS on Graph 136, page 371, they show an excess of deaths at ages 6 months and 9 months, and a corresponding decrease at ages 5 and 10 months. To smooth out this roughness, an equivalent curve, marked ADJUSTED DEATHS, was drawn graphically in such manner that the total of adjusted deaths was equal to the total of reported deaths.

Deaths during the first month of life were not plotted because they were out of proportion to those in the other months; also, those during the second month of life were entered but left unchanged.

In the table in the upper right-hand corner of Graph 136 are shown the reported deaths by months under 1 year of age; the adjusted values of these; the difference between the reported and adjusted number of deaths at each age; the per cent which this difference bears to the number of reported deaths; and in the last column to the right is shown the number of adjusted deaths at each month of age when the sum of the deaths under 1 year is reduced to 10,000.

#### DETERMINATION OF POPULATION USED IN CALCULATION OF NUMBER OF BIRTHS AND OF ANNUAL RATES OF MORTALITY UNDER 5 YEARS AND OF MONTHLY RATES OF MORTALITY UNDER 1 YEAR.

137. The population at each year of age was assumed to progress geometrically after July 1, 1900, according to the ratio determined from the population on this date and that on July 1, 1910. The

populations on both these July 1 dates were estimated arithmetically from the enumerated populations of April 15, 1910, and June 1, 1900. The ratio  $r$  is therefore expressed by means of the equation

$$r^{10} = \frac{1910\text{-July-1}P_x}{1900\text{-July-1}P_x} \quad (78)$$

and the population  $y$  years after July 1, 1900, by the equation

$$(1900\text{-July-1}) + y P_x = r^y 1900\text{-July-1}P_x.$$

The ages  $x$  are entered on the left of the tape, the values for  $1910\text{-July-1}P_x$  in the middle and those for  $1900\text{-July-1}P_x$  on the right. The 1910 values were copied from column 2 of Table 159, page 450, and the 1900 values from column 7 of Table 181, page 472. The adding machine was split between banks 16-17 and 8-9.

138. The characteristic of log 97,764, or 4, was entered in bank 9 and immediately to the right of it the mantissa, which was taken from Vega's seven place logarithm tables, so that the first bank was left vacant and was automatically filled with a zero. Beneath this is entered the complement of log 80,771, giving a subtotal .0829235, which is log  $r^{10}$ .

Throughout these calculations the process of subtracting by adding the complement of the number to be subtracted is used. In order to carry away the extra unit thus obtained on the left in the remainder, the complement is always preceded by 9's to the last bank on the left, or to the split on the left. Also, throughout these calculations the decimal point in a series of additions is often indicated by a vertical line between the two banks where the decimal point should occur. The vertical line is also used to cross out the extra units obtained in subtracting by adding complements, but the use to which the line is put can be readily distinguished.

If the decimal point is moved one place to the left, this log  $r^{10}$  becomes log  $r$ , or the logarithm of the yearly ratio of increase. This .00829235 was set up and repeated twice, making three times in all; then half of it was set up in unit's place and again in ten's place, thus adding the logarithm of the ratio of 8.5 years' increase; then log 80,771, whose complement was entered above, is added one space to the left to conform with the change of decimal point mentioned above.

This subtotal is log  $1908\text{-December-31}P_x$ , as indicated by the 1908 on the left side of the tape. The machine is split between banks 13 and 14. Then log  $r$  is added again, giving log  $1909\text{-December-31}P_x$  as subtotal, while the 1 added in bank 14 changes the date to 1909. This process was repeated until log  $1913\text{-December-31}P_x$  was obtained. Then this work was checked by setting up log  $1910\text{-July-1}P_x$  and adding to it log  $r$  repeated three times and then one-half log  $r$ , so that the total is log  $1913\text{-December-31}P_x$ , which agrees with that obtained above, as indicated by the mark ⊙.

GRAPH 136

NUMBER OF DEATHS BY MONTHS UNDER 1 YEAR ADJUSTED GRAPHICALLY

This symbol, a figure within a circle, will be used to point out identical results by different processes, thus forming a check on the work. It is unnecessary to use them where the operator is familiar with the processes; also the ages need be set down in only a very few cases, but they have been entered nearly everywhere in this description to aid the reader. Only logarithms for age 0 are obtained here, those for the other ages being obtained by the same process.

139. The antilogarithms of the logarithms which were obtained by the process indicated in tape 138, for all the ages and calendar years needed in the following computations, are entered here, those for 1908 and 1911 being set in parallel columns, as explained in section 143. Below these are the values for 1909 and 1910, and next those for 1912 and 1913, the machine being split as in tape 137.

CALCULATION OF NUMBER OF BIRTHS.

140. This work is shown in Diagram 15 and described fully in section 106, page 338. The deaths are taken from Table 159, page 450, columns 3, 4, 5, and bottom of page.

141. This work is shown in Diagram 17, page 341. The factors at the top of the diagram are set forth in Table 109 and are described in section 109, page 340. The populations shown on the diagonal lines in this diagram were obtained from tape 139 above, and their purpose is fully described in section 109.

142. The additions necessary to obtain the number of births for any calendar year and for the three-year period 1909 to 1911 are explained in section 110, page 342. The additions finally used are shown here. On the left are shown the additions to obtain the number of births in 1909 from population aged 4-5 and on

the right those to obtain the number of births in 1910 from population aged 3-4. Below the 1909 additions are those to obtain the number of births in 1911 from population aged 2-3, while to the right of this the three totals are summed to obtain the total number of births in the three-year period 1909-1911.

**CALCULATION OF ANNUAL RATES OF MORTALITY UNDER 5 YEARS  
AND MONTHLY RATES UNDER 1 YEAR.**

143. The results shown in tapes 143 to 146 are obtained in detail in Tables 111 and 112, page 343, respectively, and full explanation is given in sections 111 and 112, pages 342 and 343. The calculations are here adapted to a computer using machine.

The machine is split between banks 16-17, 9-10, and 3-4. The differences  ${}_{1911-\text{December-31}}P_x - {}_{1908-\text{December-31}}P_x$ , as obtained mentally from tape 139, are entered in banks 10 to 13. One-half these differences are entered in banks 4 to 7, the .5, where the number is odd, being entered in the last column to the right. The ages are entered in bank 17. Beneath the totals of these columns the sum of the 1908 values on the left of tape 139 is subtracted from the sum of the 1911 values on the right, while the total sum of the  $\frac{1}{2}\delta_x$  is repeated twice on the right. As indicated by the ③ mark, the totals agree in each case, thus affording a check on the work of subtraction and division.

144. As explained in section 112, page 343, since  $\frac{1}{12}$  of  $5,601 = 466 + 9/12$ ,  $\delta_x^{(12)}$  for the first nine months was taken as 467 and for the last three months as 466. Accordingly,  $\frac{1}{2}\delta_0^{(12)}$  is taken as 234 and  $\frac{1}{2}(\delta_x^{(12)} + \delta_{x+1}^{(12)})$  as 467 for the next nine months, since  $(467 + 466)/2$  was set equal to 467; then  $\frac{1}{2}(\delta_x^{(12)} + \delta_{x+1}^{(12)})$  is set equal to 466 for the next two months and  $\frac{1}{2}\delta_{x+1}^{(12)}$  to 233. In order to check these results and furnish a memorandum to the operator, 234, nine times 467, two times 466, and 233 are added in three parallel columns in tape 144, giving a total of 5,602 instead of 5,601, because  $467/2$  was taken equal to 234 and  $(467 + 466)/2$  to 467.  $\delta_x^{(12)}$  is used here for months in place of  $\delta_x$ , which is used for years.

145. The adjusted deaths by months under 1 year which are used in these computations are shown in column 3 of the table in the upper right corner of Graph 136, and the deaths for single years under 5 are found in column 6 of Table 159, page 450. To obtain those exposed to risk of death during each month of age under 1 year and during the single years under 5, equations (29) and (30), pages 342 and 343, were used. The machine was split between banks 11-12 and 7-8. On the left of the tape  $E_0$  was entered from tape 142 and to it was added the complement of  $\frac{1}{2}\delta_0^{(12)} = 234$ , giving 346,430 as subtotal. Then to this was added the complement of  $\frac{1}{2}(\delta_0^{(12)} + \delta_1^{(12)}) = 467$  and  $D_0^{(12)} = 16,404$ , and a subtotal taken. This process was repeated until 467 had been subtracted nine times, or until the number of deaths during the monthly age interval 8-9,  $D_8^{(12)} = 1,835$ ,

was subtracted. Then 466 was subtracted both with  $D_9^{(12)}$  and with  $D_{10}^{(12)}$ . This gave the exposed to risk for each of the twelve months of life under 1 year. To obtain a similar value for the year 1-2, the remainder of  $\delta_0$  or  $\frac{1}{2}\delta_{11}^{(12)}$  from tape 144 and deaths during twelfth month  $D_{11}^{(12)} = 1,600$  were subtracted, and then  $\frac{1}{2}\delta_1 = 2,449$  from tape 143, giving the subtotal 294,770. Then from this subtotal were subtracted 2,449 and 2,984 from tape 143 and  $D_1$  and a subtotal taken, from which were subtracted 2,983, 2,355, and  $D_2$ , and so on. When  $\frac{1}{2}\delta_x$  ended in .5 it was increased by unity the first time it was subtracted but not the second time. The total of the values  $\delta_x$  subtracted in tape 145 would equal  $24,874 - 1,849 + 1$ . The +1 is due to  $\frac{1}{2}\delta_0^{(12)}$  and  $\frac{1}{2}(\delta_8^{(12)} + \delta_9^{(12)})$  each being increased by .5.

Then the adding-machine paper was rolled back to the beginning of tape 145, and on the right side, opposite the subtotals on the left, the deaths by months under 1 year from column 3 of the table in the upper right-hand corner of Graph 136 and those for ages 1 to 4 years from column 6 of Table 159, page 450, were set down and a subtotal taken at the end. All these deaths except those during the 4-5 year, 1,723, were subtracted on the left side of tape 145. Accordingly, 1,723 was subtracted from this subtotal, 62,342; also the quantity 24,874 less 1,849, from tape 143, and plus 1 were added, and a subtotal taken. This subtotal is the sum of all quantities subtracted from the left of tape 145, since all the deaths except those for age 4-5 and all the  $\delta_x$  in tape 143 except the last half of  $\delta_4$  were subtracted. As explained in section 144, the 1 is due to taking  $467/2 = 234$  and  $(467 + 466)/2 = 467$ . The complement of this subtotal was set up and repeated twice and to this  $E_0$  from tape 142 was added. The total is the same as that obtained on the left of tape 145 as indicated by the mark ③.

At the same time the deaths were being entered on the right side of tape 145 the ages were entered in banks 8 and 9.

146. Then each  $D_x^{(12)}$  in tape 145 was divided by the  $E_x^{(12)} - \frac{1}{2}\delta_x^{(12)}$  opposite, and the quotient to the nearest sixth decimal place was set down on the left side of tape 146, while on the right side its complement was entered, thus giving  $10^6q_x^{(12)}$  and  $10^6p_x^{(12)}$ , respectively. The machine was split between banks 10-11 and 6-7.

A check on the  $10^6p_x$  is that the sums of  $10^6q_x$  and  $10^6p_x$  should be complements.

**OSCULATORY INTERPOLATION.<sup>1</sup>**

147. As stated in section 131 on page 364, the osculatory interpolation formula was applied to the population and deaths summed in groups 4-8, 9-13, and so on. The machine was split between banks

<sup>1</sup> A short method of constructing abridged life tables will be found in the Supplement to the Seventy-fifth Annual Report of the Registrar-General of England and Wales, Part I, Life Tables, pp. 26-33.

99999994 999,991\*

15-16 and 7-8. The population and death statistics are on page 450, columns 2 and 6, respectively, of Table 159. Beginning with age 4, this number was set up in bank 16, then  $P_4 = 86,876$  in banks 8 and 12, and  $(3d)_4 = 1,723$  on the right. Since the deaths are for a three-year period, they are indicated by  $(3d)_x$  instead of by  $d_x$ . To these last two values those through age 8-9 were added, and a total taken. Immediately below this, 9 was entered in bank 16 and the populations and deaths added from age 9-10 through age 13-14, and a total taken, and so on until the values for ages 109-113 had been added. The  $P_{135}$  was not used. These additions are shown here for only age groups 4-8 and 9-13.

148. Then the totals obtained in tape 147 were copied in tape 148, a space being left after each fifth value and also after the last values, 1 and 2, respectively. To check these totals the values for ages 0 to 3-4 years were added, as well as those beyond age 113-114. The first values were obtained by adding the totals of groups 0-4 from the left of tape 137 and from the right of tape 145, respectively, and then subtracting 86,876 and 1,723, respectively, the values for age 4. Also  $P_{135} = 1$  was added. This gives for the total population 4,605,057 and for deaths 233,498, which agree with the totals at the top of columns 2 and 6, respectively, in Table 159, page 450. The machine was split between banks 15-16 and 7-8, the ages being entered in banks 16-17. The ages in tapes 149 to 153 are the same as in tape 148, except that one age group is lost at the end every time a column is differenced. Hence the last age group in tape 149 is 104-108; in tape 150, 99-103; and so on.

149. The formula used for osculatory interpolation requires the first five quinquennial differences of  $T_x$  and  $(3l)_x$ , and they are shown in tapes 148 to 152.

To shorten the work of differencing and to increase its accuracy, all negative numbers were entered directly upon the adding machine, while only the complements of positive numbers were set up. Since all the  $\Delta T_x$  and  $\Delta(3l)_x$  were negative, they were entered directly in tape 148. This does away with the necessity for using signs and reduces the whole process of differencing to the subtraction, arithmetically, of the upper value from the one immediately below it. This subtraction was done mentally and the results entered on the adding machine. When the lower number is less than the upper one, the lower number may be supposed to be increased by unity in the first space beyond the left of the machine or beyond the split at the left. Thus, in subtracting 414,281 from 394,479, the latter was treated as though it were 100,394,479, so that subtracting 414,281 from it gives 99,980,198; this last number is the complement of +19,802 which would be obtained if +414,281 were added algebraically to -394,479.

In order to check the work of differencing as it is being done, the top value of the column being differenced was set down and a space taken between it and the first differences. Then when the first difference is set down the total appearing through the glass at the base of the machine should be the lower number. For example, the two columns in tape 149 begin as follows:

|           |        |
|-----------|--------|
| 414281    | 5796   |
| 999980198 | 997091 |

Then through the glass at the base of the machine should appear the lower numbers,

|        |        |
|--------|--------|
| 394479 | 1 2887 |
|--------|--------|

When the second set of differences have been put down:

|           |        |
|-----------|--------|
| 414281    | 5796   |
| 999980198 | 997091 |
| 11140     | 1275   |

Then through the glass at the base of the machine should appear the lower numbers,

|        |        |
|--------|--------|
| 405619 | 1 4162 |
|--------|--------|

and so on. Thus by comparing the totals through the glass at the base of the machine with the lower numbers in tape 148, after setting down each set of differences, the operator can check his work as he goes along. The totals in tape 149 are 1 and 2, which are the last values in tape 148, and this is a check on the work, but not a complete one, since compensating errors would not alter the final result. After tape 149 is completed a pencil line is drawn through  $\Delta T_4$  and  $\Delta(3l)_4$  to avoid confusing them with the  $\Delta^2 T_x$  and  $\Delta^2(3l)_x$ , respectively. The machine was split between banks 9-10 and 6-7.

150-152. In the same way the first values of tape 149 were set up in tape 150, the machine spaced, and the differences of the values in tape 149 set up. As before, the operator can check his work after entering each set of differences. The totals in tape 150 are 9,999,994 and 9,999,991, which agree with the last values in tape 149.

In the same way tape 151 is obtained from tape 150, and tape 152 from tape 151. The  $\Delta^4 T_4$  and  $\Delta^4(3l)_4$  at the top of tape 152 were subtracted at the end of this tape, so that the final totals are the sums of the fifth differences only.

153. As indicated in Table 115, page 347, the work is shortened by using  $.0016\Delta^5 T_x$  and  $.0016\Delta^5(3l)_x$ . Accordingly the fifth differences in tape 152 are multiplied by 16 and the product set up on the adding machine in tape 153 in the columns headed  $16\Delta^5 T_x$  and  $16\Delta^5(3l)_x$ . After each fifth value a subtotal was taken and a space left after each subtotal, so that these values might not be confused with the products themselves. At the end a total was taken.

Then the totals of the fifth differences in tape 152 were set once in unit's place, once in ten's place, and then one-half these totals once in ten's place, giving as sum 16 times these totals. As indicated by the mark ④, these totals agree with those obtained just above.

If they do not agree the error can be located approximately as follows: Fasten back the platen so that the tape may not be marred. Then mentally subtract the first difference in tape 151 from the middle value, that is, 5,638 from 99,992,648, setting the difference down on the adding machine, thus:

$$\begin{array}{r|l} 99,987,010 & \\ 99,870,100 & \text{which gives } 99,792,160, \\ 99,935,050 & \end{array}$$

and should be the second subtotal in tape 153. If it did not agree with this second subtotal, that would indicate that the error was above the second subtotal, so that 16 times (19,664 - 5,638) from tape 151 would be found in the same way and compared with the first subtotal in tape 153.

#### INTERPOLATION BY CONTINUOUS ADDITION.

154. As stated on page 346, the work of interpolation was carried out by continuous addition with corrected fifth differences. In order to start these additions the leading unit differences of the youngest age, that is, age 4, were required. Equations (42) for these leading unit differences, page 347, are copied as equations (79) in a slightly different order without fractions and in terms of  $T_4$  instead of  $y_4$ . In this table  $\Delta^4 T_4$ ,  $\Delta^3 T_4$ ,  $\Delta^2 T_4$ , and  $\Delta T_4$  each head the column in which are written its coefficients in the four equations given below. For example,  $10^4 \delta^3 T_4 = -96 \Delta^4 T_4 + 80 \Delta^3 T_4$ .

Equations (79)

| Leading unit differences. | $\Delta^4 T_4$ | $\Delta^3 T_4$ | $\Delta^2 T_4$ | $\Delta T_4$ |
|---------------------------|----------------|----------------|----------------|--------------|
| $10^4 \delta^4 T_4 =$     | + 16           |                |                |              |
| $10^4 \delta^3 T_4 =$     | - 96           | + 80           |                |              |
| $10^4 \delta^2 T_4 =$     | + 256          | - 320          | + 400          |              |
| $10^4 \delta T_4 =$       | - 336          | + 480          | - 800          | + 2000       |
| Totals                    | - 160          | + 240          | - 400          | + 2000       |

In order to check the work it should be noted that the sum of the factors of  $\Delta^4 T_4$  equals minus ten times the first factor; that the sum of the factors of  $\Delta^3 T_4$  equals one-half the last factor; that the sum of the factors of  $\Delta^2 T_4$  equals minus the first factor.

$\Delta^4 T_4$  from tape 151 was set up on the computing machine and multiplied by the factors in the second column of equations (79), beginning at the top. These products were entered upon the adding machine as obtained, and a space taken; then ten times the first factor was added, giving zero as a total, and thus checking these products. Where the factors in equations (79) are negative, the complements of the

products were entered instead of the products themselves.

$\Delta^3 T_4$  from tape 150 was set up on the computing machine and multiplied by the factors in the third column of equations (79), beginning at the top. These products were entered upon the adding machine as obtained and a space taken; then the sum as seen through the glass at the base of the machine was added, giving a total equal to the last product.

$\Delta^2 T_4$  from tape 149 was set up on the computing machine and multiplied by the two factors in the fourth column of equations (79). These were entered upon the adding machine, a space taken, and the first product added again, giving zero for total.

Since these three groups of products are in the same order as the factors in equations (79),  $10^4 \delta^4 T_4$  is at the top of the first group, or the third from the last of the first group;  $10^4 \delta^3 T_4$  is the sum of the two products second from the last in each of the first two groups;  $10^4 \delta^2 T_4$  is the sum of the three products next to the last in each group;  $10^4 \delta T_4$  is the sum of the three products last in each group plus +2,000 times  $\Delta T_4$ , 414,281, at the top of tape 148.

155. As a check on the additions made in tapes 158 to 161, the first four leading unit differences of some older age, near the end of the additions, were computed directly from equations (40) on page 346. For the convenience of the operator the equations are given as equations (80) in a different order, without fractions, and in terms of  $T_{x-10}$  and  $T_x$  instead of  $y_n$  and  $y_{n+2}$ . As in equations (79), the leading quinquennial differences of  $T_{x-10}$  each head a column in which are written its coefficients in the four equations for the leading unit differences of  $T_x$ .

Equations (80)

| Leading unit differences. | $\Delta^4 T_{x-10}$ | $\Delta^3 T_{x-10}$ | $\Delta^2 T_{x-10}$ | $\Delta T_{x-10}$ |
|---------------------------|---------------------|---------------------|---------------------|-------------------|
| $10^4 \delta^4 T_x =$     | - 32                | + 16                |                     |                   |
| $10^4 \delta^3 T_x =$     | - 48                | + 64                | + 80                |                   |
| $10^4 \delta^2 T_x =$     | + 48                | + 16                | + 480               | + 400             |
| $10^4 \delta T_x =$       | + 16                | - 176               | + 880               | + 3200            |
| Totals                    | - 16                | - 80                | + 1440              | + 3600            |
|                           |                     |                     |                     | + 2000            |

In order to check the work it should be noted that the sum of the factors of  $\Delta^5 T_{x-10}$  is minus the last factor; that the sum of the factors of  $\Delta^4 T_{x-10}$  is minus the sum of the first two factors; that the sum of the factors of  $\Delta^3 T_{x-10}$  is three times the central factor; and that the sum of the factors of  $\Delta^2 T_{x-10}$ , added to the first factor, is ten times the first factor.

From equations (80) it appears that the leading unit differences of  $T$  on the left are 10 years older than the leading quinquennial differences of  $T$  at the heads of the columns, from which the leading unit differences are derived. Since 89 is the age of the last  $16 \Delta^5 T_x$  in tape 157, 99 is the oldest age for which the leading unit differences can be computed accord-

CALCULATION OF THE LIFE TABLE FOR MALES IN THE STATE OF NEW YORK: 1910  
PHOTOGRAPHS OF DIAGRAMS AND ADDING MACHINE TAPES USED IN CONNECTION WITH NUMERICAL COMPUTATIONS

ing to equations (80). Hence the leading unit differences for  $T_{99}$  were computed in tape 155 as a check on the work of addition in tapes 158 to 161. In finding the leading quinquennial differences of  $T$  from tapes 148 to 152, it will be noted that 89 is the third age in the fourth group of ages in tape 148 and that it occupies a corresponding position in each of the tapes 149 to 152.

$\Delta^3 T_{99}$  from tape 152 was set up on the computing machine and multiplied by the factors in the second column of equations (80), beginning at the top, and the products were entered upon the adding machine as computed and a space taken; then the last product was added again, giving zero as total, and thus checking these products.

$\Delta^4 T_{99}$  from tape 151 was multiplied by the factors in the third column of equations (80), the products entered upon the adding machine, a space taken, and then the first two products added again, giving zero as total.

$\Delta^5 T_{99}$  from tape 150 was multiplied by the factors in the fourth column of equations (80), the products entered upon the adding machine, and a total taken. This total is three times the central factor.

$\Delta^6 T_{99}$  from tape 149 was multiplied by the factors in the fifth column of equations (80), the products entered upon the adding machine, a space taken, and the first factor added again, giving a total which is ten times the first factor.

Since these four groups of products are in the same order as the factors in equations (80),  $10^4 \delta^4 T_{99}$  is the sum of the two products third from the last in each of the first two groups;  $10^4 \delta^3 T_{99}$  is the sum of the three products second from the last in each of the first three groups;  $10^4 \delta^2 T_{99}$  is the sum of the four products next to the last in each group; and  $10^4 \delta T_{99}$  is the sum of the four products last in each group plus + 2,000 times  $\Delta T_{99}$ , 2,024, in tape 148.

To insure that the leading unit differences of  $T_4$  and  $T_{99}$  are correct, it is well to compare back the products which were copied from the groups at the beginning of tape 154 and tape 155 to obtain these leading unit differences before going on with the next step.

156. The diagrams described in section 158, page 382, are shown here so that the operator may use them in deriving the values in tape 158 from those in tape 157. The ages are  $x=4$ ,  $x=9$ , and  $x=14$ . The column  $x=9$  is put down twice, first to show the addition of its values with those in column  $x=4$ , which is parallel to it, and again just below its first position, to show the addition of its values with those in column  $x=14$ , which is below it on the left side of the tape. The point of junction between the addition of the groups  $x=4$  and  $x=9$  and that of the groups  $x=9$  and  $x=14$  is indicated by the sign  $\oplus$ . The use of these diagrams is explained fully in section 158, especially by Diagram 158, page 382.

157. In Table 115, page 347, attention is called to the fact that the factors of  $\Delta^5 y_n$  and  $\Delta^5 y_{n+1}$  in the equations

for the fifth fractional differences are all multiples of .0016, the other factors being 0, +1, +3, +5, and -6. The values of  $16\Delta^5 T_x$  are given in tape 153, and the products of these values by +1, +3, +5, and -6 were obtained upon the adding machine by repetition, as shown in tape 157. The machine was split between banks 8-9 so that two multiplications could be performed at the same time.

The first value on the left of tape 153, or 98,836,848, is set up in banks 9 to 17, inclusive, and the second value, 231,152, in banks 1 to 6, inclusive; then they are added three times by means of the repeat key and a subtotal taken. Then these two values are set up again, added twice, and a subtotal taken. Finally, they are set up a third time, added once, the machine spaced, and the complements of the two sums appearing through the glass at the base of the machine are added and a total taken. If the complements are correct the totals are zero, and the only figure appearing is the 1 in bank 9. Thus the first subtotal is the product of +3 times the first two values on the left of tape 153; the second subtotal is +5 times these two values; and the complements at the end are -6 times these two values. Then the next two values are operated upon in the same way, and so on until all the  $16\Delta^5 T_x$  on the left of tape 153 have been operated upon.

158. In section 149, where ages in the quinquennial groups 4, 9, 14, 19, and so on, are used instead of ages by single years, it was shown that  $\Delta T_4 + \Delta^2 T_4 = \Delta T_5$ ,

$$\begin{array}{r} 414,281 \\ 999,980,198 \\ \hline \text{or } 394,479; \end{array}$$

in section 150, that  $\Delta^2 T_4 + \Delta^3 T_4 = \Delta^2 T_5$ ,

$$\begin{array}{r} 99,980,198 \\ 30,942 \\ \hline \text{or } 11,140. \end{array}$$

Likewise, in section 151,  $\Delta^3 T_4 + \Delta^4 T_4 = \Delta^3 T_5$ , and in section 152,  $\Delta^4 T_4 + \Delta^5 T_4 = \Delta^4 T_5$ . Then when the age is measured in single years these equations become

$$\begin{aligned} \delta T_4 + \delta^2 T_4 &= \delta T_5 \\ \delta^2 T_4 + \delta^3 T_4 &= \delta^2 T_5 \\ \delta^3 T_4 + \delta^4 T_4 &= \delta^3 T_5 \\ \delta^4 T_4 + \delta^5 T_4 &= \delta^4 T_5 \end{aligned}$$

Making these equations general by using age  $x$  instead of 4 and reversing their order:

$$\begin{aligned} \delta^4 T_x + \delta^5 T_x &= \delta^4 T_{x+1} \\ \delta^3 T_x + \delta^4 T_x &= \delta^3 T_{x+1} \\ \delta^2 T_x + \delta^3 T_x &= \delta^2 T_{x+1} \\ \delta T_x + \delta^2 T_x &= \delta T_{x+1} \end{aligned}$$

CALCULATION OF THE LIFE TABLE FOR MALES IN THE STATE OF NEW YORK: 1910  
PHOTOGRAPHS OF DIAGRAMS AND ADDING MACHINE TAPES USED IN CONNECTION WITH NUMERICAL COMPUTATIONS

Since  $\delta^4 T_{x+1} = \delta^4 T_x + \delta^5 T_x$ , the column of  $\delta^4 T_x$  was obtained by continued addition of the successive  $\delta^5 T_x$ , a subtotal being taken after the addition of each unit fifth difference.  $10^4 \delta^4 T_4$ , 90,208, computed in tape 154, begins the column of  $10^4 \delta^4 T_x$  in tape 158 which is derived by continuous addition of the successive values of  $10^4 \delta^5 T_x$ . The remainder of section 158 explains how these successive values of  $10^4 \delta^5 T_x$  are obtained from tape 157. To learn the mechanical processes necessary to obtain tape 158 from tape 157 it is necessary to study only—

- (1) Table 130 in connection with tape 157.
- (2) Diagram 158, page 382, in connection with Table 130 and Diagram 156, page 377.
- (3) Diagram 158 in connection with tape 158.
- (4) Tape 157 in connection with Diagram 156 and tape 158, assuming that tape 157 ends with the ages 94 and 99, for which the products are all zeros, just as those for  $x = 4 - 10$  and  $x = 9 - 10$  in Table 130 were all zeros.

For convenience of reference the right side of Table 115, page 347, is copied with some changes as equations (81). The variable  $T$  is used instead of  $y$ ; the ages  $x - 10$ ,  $x - 5$ ,  $x$ ,  $x + 1$ ,  $x + 2$ , etc., to  $x + 5$ , instead of  $n$ ,  $n + 1$ ,  $n + 2$ ,  $n + 2.2$ ,  $n + 2.4$ , etc., to  $n + 3.0$ , and the fractions eliminated.

Equations (81)

| Unit fifth differences. | $16\Delta^5 T_{x-10}$ | $16\Delta^5 T_{x-5}$ | $16\Delta^5 T_x$ |
|-------------------------|-----------------------|----------------------|------------------|
| $10^4 \delta^5 T_x$     | = +5                  | 0                    |                  |
| $10^4 \delta^5 T_{x+1}$ | = +3                  | +1                   |                  |
| $10^4 \delta^5 T_{x+2}$ | = -6                  | 0                    |                  |
| $10^4 \delta^5 T_{x+3}$ | = 0                   | -6                   |                  |
| $10^4 \delta^5 T_{x+4}$ | = +1                  | +3                   |                  |
| $10^4 \delta^5 T_{x+5}$ | =                     | +5                   | 0                |

Equations (81) give the equations for the unit fifth differences from  $10^4 \delta^5 T_x$  to  $10^4 \delta^5 T_{x+5}$ , which are the five  $10^4 \delta^5 T_x$  necessary to pass from one quinquennial age group to another in the continuous addition in tape 158. The  $16\Delta^5 T_{x-10}$  and  $16\Delta^5 T_{x-5}$ , which will be obtained from tape 157, each head a column in which are written its coefficients in the six equations (81). It will be noted that those two factors are for ages 10 and 5 years younger, respectively, than the quinquennial age group in which the unit fifth differences of this table occur.

According to tape 148 the leading quinquennial differences of  $T$  are for ages 4, 9, 14, and so on. To find the equation for the unit fifth difference of  $T$  at any age, the quinquennial age group in which the age occurs is first noted. For example, in finding the equation for the unit fifth difference of  $T$ , it is first noted that 7 occurs in the quinquennial age group 4-8 and  $7 = 4 + 3$ . Then 4 is substituted for  $x$  in the expressions at the head of columns 2 and 3 in equations (81) and also in the expression  $10^4 \delta^5 T_{x+3}$ , so that

$$10^4 \delta^5 T_{7-4+3} = (0)(16\Delta^5 T_{4-10}) + (-6)(16\Delta^5 T_{4-5-9-10}).$$

Again,

$$10^4 \delta^5 T_{13-10+3} = 10^4 \delta^5 T_{9+4} - (+1)(16\Delta^5 T_{9-10}) + (+3)(16\Delta^5 T_{9-5-4})$$

and

$$10^4 \delta^5 T_{15-12+3} = 10^4 \delta^5 T_{14+1} - (+3)(16\Delta^5 T_{14-10-4}) + (+1)(16\Delta^5 T_{14-5-9}).$$

In order to obtain rapidly the successive  $10^4 \delta^5 T_x$  from the products in tape 157, Table 130 should be studied. The ages are at the top of this table and any number in the table is the product of the  $16\Delta^5 T_x$  whose age  $x$  is at the head of the column and of the corresponding factor on the same line in the first column on the left. The order of these factors in the first column on the left is the same as that of the products in tape 157, the numbers in this table being taken from that tape. Hence, learning to pick out the successive  $10^4 \delta^5 T_x$  from this table will enable one to obtain them rapidly from tape 157.

Table 130

| PRODUCTS OF $16\Delta^5 T_x$ FOR $x = 4 - 10$ , $9 - 10$ , $4$ , $9$ , $14$ , AND $19$ , BY THE FACTORS $+1$ , $+3$ , $+5$ , AND $-6$ . |                                                    |              |          |          |          |          |

| -6                                                                                                                                      | 0                                                  | 0            | 6978912  | 98013088 | 83231776 | 17961408 |

NOTE.—The age is at the head of the column in which the product occurs, while the other factor is in the first column of Table 130 on the same line with the product.

Since the interpolated values of  $T$  from ages 4 to 13 were determined from a constant fourth difference formula according to section 116, page 347, the fifth unit differences from ages 4 to 9, both inclusive, must be zero, or, in other words, the fourth unit differences from ages 4 to 10, both inclusive, are constant. In Table 130 this fact is indicated by two columns of zeros corresponding to the ages 4-10 and 9-10. These ages are used because from equations (81) it will be seen that the fifth unit differences from  $10^4 \delta^5 T_4$  to  $10^4 \delta^5 T_{8-4+4}$  would be obtained from  $16\Delta^5 T_{4-10}$  and  $16\Delta^5 T_{4-5-9-10}$ , which equal zero, according to Table 130. Hence all these five unit fifth differences are equal to zero. The equations and values for the unit fifth differences of  $T_x$  for ages 9 to 14 are shown in Table 131.

On the left side of Table 131, under the caption "From equations (81)," are shown equations (81) with 9 substituted for  $x$ . On the right side, under the caption "From Table 130," are the products from Table 130 which correspond to the two members on the right side of each of these equations. Thus

$$10^4 \delta^5 T_9 = +5(16\Delta^5 T_{9-10}) + 0(16\Delta^5 T_{9-5-4})$$

according to equations (81) and

$$= 0 + 0$$

according to Table 130.

| $10^4\delta^5T_{19=14+5}$                                                                            | -                       |                        |   | +5              | -     |         |
|                                                                                                      |                         |                        |   |                 |       | 1155760 |

In Table 133 the part from equations (81) is omitted, since it varies only in the ages of the  $16\Delta^5T_x$  and  $10^4\delta^5T_x$ . Also the first age is 20 = 19 + 1 instead of 19. On the left of Table 133,  $10^4\delta^5T_x$  from ages 20 to 24 requires  $16\Delta^5T_{10-10=0}$  and  $16\Delta^5T_{10-5=5}$ , while on the

right  $10^4\delta^5T_x$  from ages 25 to 29 requires  $16\Delta^5T_{24-10=14}$  and  $16\Delta^5T_{24-5=19}$ . Hence only the part from Table 130 is set down in Table 133.

| 29 = 24 + 5                                                                                                    | -                       |          |                           |                         |    | 85032180 |

If, in picking out the values in the columns headed 9-10, 4, 9, 14, and 19 in Table 130 which are required in Tables 131, 132, and 133, one were to trace with a pencil from one value to another in Table 130 as they are selected, a certain symmetry in the tracing would be found. This tracing for the columns headed 4-10, 9-10, 4, 9, and 14 is shown in Diagram 158.

While nominally each of the five successive  $10^4\delta^5T_x$  in Tables 131 to 133 is the sum of two terms, three of them contain zero as one term. From equations (81)

$$10^4\delta^5T_{x+1} = +3(16\Delta^5T_{x-10}) + 1(16\Delta^5T_{x-5}),$$

while

$$10^4\delta^5T_{x+4} = +1(16\Delta^5T_{x-10}) + 3(16\Delta^5T_{x-5}).$$

From Tables 131, 132, and 133 it is apparent that the sum of the two terms, either of  $10^4\delta^5T_{x+1}$  or of  $10^4\delta^5T_{x+4}$ , can not be obtained readily by mental addition. Accordingly, in place of their sum, both terms were entered upon the adding machine before a subtotal was taken. Where two products must both be added before taking a subtotal, they are connected by solid lines in Diagram 158; the rest of the tracing is dotted lines.

Diagram 158.—OUTLINE TO SHOW METHOD OF DERIVING TAPE 158 FROM TAPE 157.

In making tape 158 it will be noted that a subtotal, marked by  $s$ , is taken after the addition of each  $10^4\delta^5T_x$ , or of each unit fifth difference. These unit fifth differences are numbered in Diagram 158 by small figures in breaks in the connecting lines. Then in tape 158 subtotals are taken, even when only zeros are added. Hence, after the 90,208 from tape 154 was entered upon the adding machine according to instructions on the left of Diagram 158, it was subtotaled six times to indicate the addition of six zeros from the columns  $x=4-10$  and  $x=9-10$ .

The seventh unit fifth difference is the sum of a zero in column  $x=9-10$  and 98,836,848 from column  $x=4$ , while the eighth unit fifth difference is zero from column  $x=9-10$ . In tape 158 it will be noted that the addition of this last zero is indicated by taking two subtotals after the addition of 98,836,848. The ninth unit fifth difference is 6,978,912 from column  $x=4$ , while the tenth unit fifth difference is the sum of zero from column  $x=9-10$  and 96,510,544 from column  $x=4$ . The eleventh unit fifth difference is 94,184,240 from the column  $x=4$ , while the twelfth

[illegible]

unit fifth difference takes 96,510,544 from that column and 231,152 from column  $x=9$ .

The above process was repeated until all the products in tape 157, including two columns of zeros for ages  $x=94$  and  $x=99$ , just beyond ages  $x=84$  and  $x=89$ , had been used. Because of these two columns of zeros the subtotal after the addition of  $+1(16\Delta^5T_{89})$ , or 15,856, and  $+3(16\Delta^5T_{94})$ , or 0, was repeated seven times altogether, indicating that the unit fourth difference for ages 90 to 96, both inclusive, is a constant, or that  $T_x$  for ages 90 to 99, both inclusive, were derived from a constant fourth difference formula.

⊙ marks  $10^4\delta^5T_{99}$ , which appears just before  $10^4\delta^5T_{99}$  or  $10^4\delta^5T_{94+5}$  is added, and also ⊙ marks the first unit fourth difference in tape 155, to show that values of  $10^4\delta^5T_{99}$  obtained by the two methods are identical.  $10^4\delta^5T_{99}$ , according to the first of equations (81) on page 380, is  $+5$  in  $x=89$  in tape 157; hence  $10^4\delta^5T_{99}$  appears just before it is added, or just above 79,280. The agreement of these two values marked ⊙ is a check on all the additions thus far.

159. The first quantity in tape 158 and all the subtotals which follow it form the  $10^4\delta^5T_x$  which are needed to build up the  $10^4\delta^5T_x$  in tape 159. Hence, starting with  $10^4\delta^5T_4$  from tape 154, or 1,934,112, the fourth unit difference, 90,208, is added seven times from tape 158, a subtotal being taken after each addition; then 98,927,056 is added and a subtotal taken, and so on until all the subtotals and the total in tape 158 are added. In order to carry the extra unit, obtained in subtracting by adding complements, one bank farther to the left, another 9 was set down in bank 9 of tape 159 before all subtotals in tape 158 that had 9 in bank 8.

⊙ marks  $10^4\delta^5T_{99}$  in tape 159 and also in tape 155, showing that the results by the two processes agree, and thus checking the values in tape 159 up to this point. As  $10^4\delta^5T_{99}$  appears just before the addition of  $10^4\delta^5T_{99}$ , so  $10^4\delta^5T_{99}$  appears just above the addition of  $10^4\delta^5T_{99}$ , or 99,949,264, which is marked with ⊙ in tape 158.

160. In the same way  $10^4\delta^5T_x$  is built by starting with  $10^4\delta^5T_4$  from tape 154, or 983,621,088, and adding  $10^4\delta^5T_4$ , or 1,934,112, at the beginning of tape 159, and taking a subtotal. Then the first subtotal in tape 159, or 2,024,320, is added and a subtotal taken, and so on until all the subtotals and the total in tape 159 are added.  $10^4\delta^5T_{99}$  is marked by ⊙, and it agrees with the value obtained in tape 155.  $10^4\delta^5T_{99}$  is easily found, since it is the subtotal just above the addition of  $10^4\delta^5T_{99}$  which is marked ⊙ in tape 159.

161. In the same way  $10^4\delta^5T_x$  is built up by starting with 857,361,392 from tape 154 and adding the  $10^4\delta^5T_x$  from tape 160. The value for age 99 is marked by ⊙, and is found to agree with the value obtained in tape 155.

162-168. The additions for the deaths are performed in exactly the same way as the additions for the populations in tapes 154 to 161. It was found convenient when copying the subtotals from the tape to throw it over a rack just back of the machine and use both hands in running the machine. However, the arrangement in tapes 162 and 163 is slightly different from that in tapes 154 and 155, since the products of the leading quinquennial differences of  $(3l)_4$  by the factors in equations (79) on page 376 are shown on the left of tape 162 and the leading unit differences of  $(3l)_4$  are shown on the left of tape 163, while the products of the leading quinquennial differences  $(3l)_{99}$  by the factors in equations (80) on page 376 and the leading unit differences of  $(3l)_{99}$  are shown on the right of tapes 162 and 163, respectively.

169. The  $\delta T_x$  or  $L_x$  determined in tape 161 are all as of 1910-July-1, while the deaths,  $\delta l_x$  or  $d_x$ , are for the three-year period 1909-1911. Hence they are written  $(3d)_x$ . In order to determine  $q_x = d_x / (L_x + .5d_x)$ , it was found convenient to write this formula  $q_x = (3d)_x / (3L_x + 1.5d_x)$ . The  $(3d)_x$  are not all divisible by 3 exactly; hence approximate values of  $d_x$  would have to be used if  $q_x$  were computed from the first form of the equation. Also it was found that  $3L_x$  could be computed more quickly and accurately than  $\frac{1}{2}(3d)_x$ , for  $L_x$ , or  $10^4\delta^5T_x$  from tape 161, was set up on the adding machine and repeated three times by means of the repeat key; then to this was added  $\frac{1}{2}(3d)_x$ , or  $\frac{1}{2}$  of  $10^4\delta^5(3l)_x$  from tape 168. This operation is shown in tape 169.

First the tapes 161 and 168 were laid off in groups of five with a pencil, as indicated on the tape. Then these two tapes were pinned together so that corresponding ages stood exactly opposite each other, and both tapes were placed over the rack at the back of the adding machine. In this way one could easily set up the consecutive  $L_x$  and add to each  $3L_x$  one-half the  $(3d)_x$  for the same age. This division was performed mentally. In tape 169 this process is shown for only ten ages.

Since in determining the rate of mortality at any age the number of deaths in tape 168 is the dividend and the number exposed to risk of death in tape 169 is the divisor, and both are carried to four places of decimals, no further attention need be given their places of decimals. While  $10^4$  appears at the head of tapes 170, 171, and 172, it is not used in describing these tapes.

170. The tape 169 was then marked off in groups of fives with a pencil, and the sums of  $3L_x + 1.5d_x = 3l_x$  were added in groups of five. Only two of these groups are shown in tape 170.

171. As a check on the work determining  $3l_x$  and also on all the work by osculatory interpolation up to this point,  $3\Delta T_x + 1.5\Delta(3l)_x$  was found for each of the ages shown in tape 148. Each sum in tape 170 is marked with a numeral surrounded by a circle, and

# OSCULATORY INTERPOLATION—DEATHS.

387

CALCULATION OF THE LIFE TABLE FOR MALES IN THE STATE OF NEW YORK: 1910

this same symbol is placed before the sum in tape 171 which should agree with it. As stated before, these marks are merely for the convenience of the reader and are not used in the computations.

172. For convenience in determining  $q_x$  the values in tape 168, or  $(3d)_x$ , were added in groups of five and three spaces left between each group so as to correspond to the sums  $(3l)_x$  in tape 170. The two tapes were pinned together so that populations and deaths for corresponding ages stood opposite each other, and then placed so that they could be conveniently read by the operator of the calculating machine on which the values of  $q_x = (3d)_x / (3L_x + 1.5d_x)$  were determined to the nearest sixth decimal place. The sums of the  $(3d)_x$  from tape 168 in groups of five should equal the  $\Delta(3l)_x$  for corresponding ages on the right of tape 148, and this serves as a check on the copying in tape 172.

173. Then each  $10^6(3d)_x$  in tape 172 was divided by the corresponding  $10^6(3l)_x$  in tape 170 and the quotient to the nearest sixth decimal place was entered on the left of tape 173 under the caption  $10^6q_x$ . As in tape 146,  $10^6q_x$  was entered on the left of the machine and  $10^6p_x$  on the right, the machine being split between banks 10-11 and 6-7. After the values for age 9 were entered a subtotal was taken as a check on the work, as the subtotals of these two columns should be complementary. This was repeated after each group of five values.

After the entry of the first value, that is, for age 4, the machine was spaced by adding 5 in bank 7 to indicate the first age in the following group of five values. Then the addition of each  $10^6p_x$  in the next group increased the number in bank 7 by unity, so that age 10 appears in banks 7-8 in the next subtotal, thus indicating the first age in the next group. In this way the ages were recorded automatically and exactly until about age 65, when the values of  $10^6p_x$  have become so small that they do not always increase the number in bank 7 by unity.

**RATES OF MORTALITY AT OLDER AGES DETERMINED FROM POPULATIONS AND DEATHS GRADUATED FROM THE ORIGINAL STATISTICS GROUPED IN ALL FIVE QUINQUENNIAL AGE GROUPS.**

174. On the left of this tape are shown the populations from age 80 to age 114, summed in all five possible quinquennial groups. On the right of the tape are shown the deaths added in the same way. The populations and deaths by single ages were obtained from page 450, columns 8 and 12, respectively, of Table 159. The column in the middle of tape 174 shows the first age of each quinquennial group. For instance, 80 signifies that 15,543 is the sum of  $L_x$  between ages 80 and 84, both inclusive, while 7,840 is the sum of the deaths for the same ages. Again, 81 indicates that 12,461 is the sum of the populations between ages 81 and 85, both inclusive, while 7,081 is the sum of the deaths between these ages. To obtain these three columns the machine was split between banks 6-7 and 10-11.

The process of adding in all groups is as follows:

First, the populations and deaths, ages 80 to 84, were added and a subtotal taken. Then 4,836 and 1,925, the values for age 80, were subtracted from the two subtotals, respectively, by setting up their complements preceded by nines, and 1,754 and 1,166, respectively, the values for age 85, were added and subtotals taken; these subtotals are the sums of the quinquennial groups aged 81 to 85, as indicated by the 81 in the middle column. In the same way the sums of the groups aged 82 to 86 were obtained by subtracting the values for age 81 and adding the values for age 86 and taking a subtotal. This process was repeated until the sums for the age group 110 to 114 were obtained, when a total was taken.

As a check on this work the sums of the groups aged 110 to 114 were added independently. These totals agree with those obtained above, as indicated by the mark  $\oplus$ . The populations and deaths on the tape were then checked back to those in columns 8 and 12, respectively, of Table 159, from which they were copied. The middle column, indicating the age groups, was obtained by setting up 8 in bank 8 while the platen is back, so that it does not appear until the first subtotal is taken. Since the machine is split between banks 6-7, a zero appears in bank 7, and this column is increased by unity after each subtraction when one is carried over to bank 7 from the nines.

175. The results in tape 174 were next arranged so that the sums of the same group followed one another according to ages, that is, group 80-84 was followed by 85-89, and that by 90-94, while the group 81-85 was followed by 86-90, and so on. This was necessary in order to perform the required differencing.

Since the equations (46) and (47) on page 349 call for  $.2\Delta T_x$ ,  $.008\Delta^3 T_{x-5}$ ,  $.2\Delta(3l)_x$ , and  $.008\Delta^3(3l)_{x-5}$ , it was found convenient in tape 175 to set down  $-2\Delta T_x$  and  $-2\Delta(3l)_x$  instead of just  $-\Delta T_x$  and  $-\Delta(3l)_x$ . The multiplication by two was performed mentally. As in tape 174, the population is on the left of the tape and the deaths on the right, the machine being split between banks 6-7 and 11-12.

176. This is merely a summation of the  $-\Delta T_x$  and the  $-(3l)_x$  in tape 174. It is used for checking purposes, and begins with age 85 instead of with age 80, for reasons explained in section 183. When age 105 is reached a subtotal is taken, and then ages 80 to 84 and ages 106 to 110 are added before a second subtotal is taken, which is then set up on the machine and added, giving for totals twice the sums of the columns. As indicated by the marks  $\oplus$ , these agree with the totals in tape 175 and afford a check upon that work.

177. Equations (46) and (47) on page 349 require only the first and third differences, and, since the latter is the second difference of the former, it can be obtained correctly by reversing the usual process of differencing, that is, by subtracting  $\Delta T_{x+5}$  from  $\Delta T_x$  and  $\Delta^2 T_{x+5}$  from  $\Delta^2 T_x$ , instead of subtracting  $\Delta T_x$  from  $\Delta T_{x+5}$  and  $\Delta^2 T_x$

from  $\Delta^2 T_{x+3}$ . It was found more convenient to use the former method, and the differencing of tape 175 to obtain the values in tape 177 and of tape 177 to obtain the values in tape 178 was performed mentally by this method, the results being set down on the adding machine.

At the end of each column of second differences the machine was spaced and the last value in the first difference column added, and a total struck. This serves as a check on the differencing, since the total should equal the first value of the first difference column, as indicated by the mark  $\textcircled{c}$ . In the same way the mark  $\textcircled{c}$  points out that the total of the second differences plus the last value in the second group of first differences equals the first value in that group.

178. The groups in tape 177 were differenced mentally by the same method as were those in tape 175, and the results set down in tape 178. A subtotal was taken after each group of third differences and to this subtotal the last value of the group being differenced was added, which should equal the first value of the group being differenced. This equality is indicated for the first group by the mark  $\textcircled{c}$ .

179. Tape 178 gives twice the third differences of  $T_x$  and  $(3l)_x$ , but equations (46) and (47) on page 349 require eight times the third differences, so that the values in tape 178 were multiplied by 4. This operation was performed mentally and the results set down in tape 179, a total being taken after each group. After all five groups in tape 178 were multiplied the subtotals of each of these five groups were multiplied mentally by four and the results set down at the end of tape 179, a total being taken. As indicated by the mark  $\textcircled{c}$ , these last five products were compared with the totals of each of the above five groups, since they serve as a check on the work in tape 179.

180.  $10^3 L_x$  and  $10^3 (3d)_x$  were obtained according to equations (46) and (47), respectively, on page 349. These equations are copied below cleared of fractions and with  $-\Delta T_{x-2}$  and  $-\Delta(3l)_{x-2}$  substituted for  $u_x$ , and  $(3d)_x$  for  $d_{x+2}$ .

$$\begin{aligned} 10^3 L_x &= -200\Delta T_{x-2} - (-8\Delta^2 T_{x-7}), \\ 10^3 (3d)_x &= -200\Delta(3l)_{x-2} - [-8\Delta^2(3l)_{x-7}]. \end{aligned} \quad (82)$$

The first quantity on the right of each equation was obtained from tape 175, beginning with the second quantity in each group, and to multiply it by 100 it was set down in the hundreds place on the adding machine. Thus 11.360 and 8.372 in tape 175 read 1,136,000 and 837,200 in tape 180. The last quantity in each equation was obtained from tape 179, and, since it was subtracted, its complement, preceded by nines, was set up on the adding machine. Thus 45,072 and 6.632 in tape 179 are entered as 9,954,928 and 9,993,368 in tape 180. The machine was split between banks 7-8 and 10-11.

In making tape 179 care was taken that the distance between any two groups in it be the same as that between any two groups in tape 175; consequently, when

the two tapes were pinned together so that the top number in tape 179 stood opposite the second one in tape 175, this same condition held in each of the other four groups. Hence the operator had only to set up any number in tape 175 in the hundreds place and add to it the complement of the number in tape 179 standing opposite it. Accordingly, the first and last numbers in each group in tape 175 were not used, because no numbers in tape 179 stood opposite them.

In order to have the ages in tape 180 run consecutively, the second number in each of the five groups of tape 175 were added before beginning with the third number of the first group, and then the third number in each group was added before beginning the fourth number of the first group. This can readily be understood by noticing the ages in tape 175. The first group in tape 175 contains seven ages, while the others contain only six. Hence the last age in tape 180 is 107, while the first age is 87.

181. For the same reasons as those described in section 169, it was found convenient to use the formula

$$\begin{aligned} q_x &= (3d)_x / (3L_x + 1.5d_x) \\ \text{instead of} \quad q_x &= d_x / (L_x + .5d_x). \end{aligned}$$

Hence, in tape 181 the value of the denominator  $3L_x + 1.5d_x$  was found by repeating three times on the adding machine each of the values on the left of tape 180 and adding to this one-half of the corresponding value on the right of the tape. To save time and space, two additions were performed at the same time by splitting the machine between banks 10-11. Hence the addition for  $x=87$  is on the left of tape 181 and for  $x=88$  on the right.

182. In the same way that values found in tape 169 were added in groups of five in tape 170, so the values found in tape 181 were added in groups of five on the left of tape 182, only in this case subtotals are obtained between groups instead of totals.

The values of  $10^3(3d)_x$  from tape 180 were copied on the right of tape 182 so that they stand opposite the  $10^3(3l)_x$  of the same age: accordingly, to determine  $q_x$  the operator had only to divide the number on the right by the one opposite it on the left.

183. This serves only as a check on the work from tape 175 to tape 182, especially from tapes 180-182. Since

$$\begin{aligned} 3l_x &= 3L_x + \frac{1}{2}(3d)_x, \\ 10^3(3l)_x &= -600\Delta T_{x-2} - 100\Delta(3l)_{x-2} \\ &\quad - 3(-8\Delta^2 T_{x-7}) - \frac{1}{2}[-8\Delta^2(3l)_{x-7}], \end{aligned}$$

when the values for  $10^3 L_x$  and  $10^3 (3d)_x$  from equations (82) are substituted. The ages in tape 181 are the same as those in tape 180; hence the total of the quantities on the left of tape 182 is equal to

$$\begin{aligned} 10^3 \sum_{x=87}^{x=107} (3l)_x &= -600 \sum_{x=85}^{x=105} \Delta T_x - 100 \sum_{x=85}^{x=105} \Delta(3l)_x \\ &\quad - 3 \sum_{x=80}^{x=100} (-8\Delta^2 T_x) - \frac{1}{2} \sum_{x=80}^{x=100} [-8\Delta^2(3l)_x]. \end{aligned} \quad (83)$$

CALCULATION OF THE LIFE TABLE FOR MALES IN THE STATE OF NEW YORK: 1910  
 PHOTOGRAPHS OF ADDING MACHINE TAPES USED IN CONNECTION WITH NUMERICAL COMPUTATIONS.

|                                                                                                                                                                                                                                                                                                                 |  |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |  |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |  |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |  |  | -----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|

The first two sums on the right side of this equation are obtained from the first subtotals in tape 176, or 22,882 and 19,331, respectively, while the last two sums are obtained from the totals at the end of tape 179, or 292,160 and 141,648, respectively. In order to multiply the two subtotals in tape 176 by 100 they are entered on the left and right sides of tape 183, respectively, in the hundreds column, the machine being split as in tape 182. Then to the quantity on the left is added one-half of its value in the thousands column to obtain 600 times 22,882. The complement of the last total on the left of tape 179, or 292,160, is repeated three times on the left of tape 183, while the complement of one-half the last total on the right of tape 179, or  $\frac{1}{2} \times 141,648 = 70,824$ , is added on the right of tape 183, and a subtotal taken. The subtotal on the left is the sum of the first and third quantities in the equation just above, while the subtotal on the right is the sum of the second and fourth quantities on the right of this equation. From equations (82) it will be seen that the subtotal on the right

of tape 183 is also  $\frac{1}{2} \sum_{x=87}^{x=107} (3d)_x$ . Hence this subtotal is added on both sides of the tape, giving a total on the left which equals the corresponding total in tape 182, as indicated by the mark  $\oplus$ , and a total on the right equal to the corresponding total in tape 182, as indicated by the mark  $\oplus$ .

184. By dividing each number on the right of tape 182 by the corresponding number on the left,  $q_x$  was obtained to the nearest sixth decimal place. Since the average of these death rates added in fives are the death rates required, the first five values were added on the machine and a subtotal taken, which is  $10^6 \sum_{x=87}^{x=91} q_x$ . Then the first value was subtracted by setting up its complement preceded by nines and the sixth value added and a subtotal taken, which is  $10^6 \sum_{x=88}^{x=92} q_x$ . This process was repeated until the last group, ages 103 to 107, was obtained, when a total was taken.

The machine was split between banks 9-10, and 89, the central age of the group 87 to 92, was entered in banks 10 and 11 opposite the first subtotal; the nines in the subtraction raise this age by unity after a subtotal, so that the number in the banks 12 to 10 is the central age of the quinquennial group whose sum is the subtotal.

185. Then the last five  $10^6 q_x$  in tape 184 were added independently in tape 185 as a check on the work in tape 184. The mark  $\oplus$  indicates that the same total was obtained for this group in both tapes 184 and 185.

186. According to the description of this process in section 118, page 349, the average rate of mortality for any age indicated in tape 184 is one-fifth of the subtotal that stands opposite it. This division was performed mentally by multiplying by two and dividing by

ten, which gives a decimal in the quotient. The adding machine was split between banks 3-4, 5-6, and 14-15. The age is entered in the banks 15-17, the integral part of the quotient in the banks 6-11, and the fractional part in the banks 1-3. Thus the first entry in tape 186 is 89 on the extreme left; then  $2 \times 1,221,737$  gives 244,347 in the central group and 4 on the extreme right. When the fractional part is .5 or over, it was preceded by nines and the number in bank 6 increased by unity. These quotients were subtotaled in groups of five for convenience in checking. At the end the 10 tenths, or 1 unit, was added to the sum of the central group, giving a total of 6,361,003.

187. The machine was then split between banks 9-10 and the subtotals in tape 184 added in two columns, beginning with age 89 on the left and age 99 on the right and taking subtotals after each fifth value. At the end the subtotal on the left was added to that on the right and a total taken. Then the total of tape 186 was repeated five times, giving a total equaling that just obtained, as indicated by the mark  $\oplus$ .

#### RATES OF MORTALITY AT OLDER AGES DETERMINED BY APPLICATION OF WITTSTEIN'S FORMULA TO THE AVERAGED RATES FROM ALL FIVE QUINQUENNIAL GROUPS.

188. In sections 117 to 119 the use of the Wittstein formula to obtain rates of mortality at the older ages is explained. As stated there, the constants of the Wittstein formula were based on rates of mortality for ten consecutive ages, taken from tape 186. Before selecting these ages the quinquennial differences of the rates of mortality in tape 186 were found, that is,  $q_{x+5} - q_x$ . This differencing was performed mentally and the results set down on the right side of tape 188. A subtotal was taken after each fifth value to aid in checking this work. On the left of tape 188 is shown a check on the differencing on the right. It will be noted that

$$\sum_{x=89}^{x=100} (q_{x+5} - q_x) = \sum_{x=101}^{x=105} q_x - \sum_{x=89}^{x=93} q_x.$$

The first sum on the right side of the equation is obtained by adding on the left of tape 188 the last five rates of mortality in tape 186, while the second sum is the first subtotal in tape 186. Hence to the first sum is added the complement of 1,348,051, and the total, marked  $\oplus$ , agrees with the sum of the differences on the right of tape 188.

Then as a basis for the calculation of the Wittstein constants the ten consecutive rates of mortality in tape 186 from ages 94 to 103 were selected. No hard and fast rule of selection applicable to all the tables could be fixed upon, owing to the irregularity of the rates obtained at these advanced ages. In some cases the rates began to decrease and in others exceeded unity. The selection, therefore, was a matter of judgment and was made so as to avoid decreasing rates and intervals where great irregularities appeared.

CALCULATION OF THE LIFE TABLE FOR MALES IN THE STATE OF NEW YORK: 1910  
 PHOTOGRAPHS OF ADDING MACHINE TAPES USED IN CONNECTION WITH NUMERICAL COMPUTATIONS

189. Equations (48) and (49) for the Wittstein constants, section 119, page 349, require  $\log(-\log q_x)$ . In the Bauschinger and Peters logarithm tables that were used the natural numbers which begin with 1 can be read directly to six figures, while those beginning with 2 or higher numbers can be read directly to only five figures. Hence the increase in  $\log q_x$ , due to its sixth figure, was obtained by interpolation.

Since the rates of mortality selected,  $q_{94}$  to  $q_{103}$ , have six significant figures preceded by a decimal point, the characteristic of their logarithms is  $-1$ , so that the logarithm of any one of these rates of mortality is a negative quantity and equal to the complement of its mantissa, or  $-\log q_x$  equals the complement of the mantissa of  $\log q_x$ .

On the left of tape 189 are shown  $-\log q_x$  for  $x=94$  to  $x=98$ , and on the right side for  $x=99$  to  $x=103$ . The machine was split between banks 8-9 and 9-10. The mantissa, 48,494,013, of the logarithm of the first five figures of  $q_{94}$  was entered on the left side of the machine and beneath it the interpolation, 569, for the sixth figure of  $q_{94}$ . To this was added the complement of the sum, which was read through the glass at the base of the machine, and a total was struck. Of course, the proof that the complement is correct is that the total is zero. This process was repeated for the next four rates of mortality, that is, for ages 95 to 98. Then the platen was rolled back to the beginning of tape 189, and  $-\log q_x$  for  $x=99$  to  $x=103$  were obtained in the same way on the right side of the machine. These last five values left 1 in bank 9 of the total, but this causes no confusion.

190. Since the  $-\log q_x$  in tape 189 have eight figures, three interpolations had to be added to the mantissa of the logarithm of the first five figures of  $-\log q_x$ : then the complement of the sum, read through the glass at the base of the machine, was added. In all cases the interpolations were taken to the nearest first decimal place, but the last number of the complement was not used, except that when it was five or over the next figure to the left was increased by unity. Of course, all the complements are negative numbers.

Since a set of Wittstein constants was to be found from each set of values shown in tape 189, that is, for ages 94 to 99, for ages 95 to 100, and so on, the  $\log(-\log q_x)$  for each of the pairs of values were grouped together by entering the first pair on the left of the machine, the second on the right, the third on the left, and so on, the values for the younger age in each pair being found just above those for the older age. The machine was split between banks 8-9 when the left side was used and between banks 9-10 when the right side was used.

191. The next value required to determine  $n$  is

$$\log(-\log q_x) - \log(-\log q_{x+5}).$$

This was done mentally by taking the difference between the two values in each of the five groups in tape

190, the difference being set down on the adding machine in tape 191, and a total taken. As stated in section 190, only eight figures of the  $\log(-\log q_x)$  were used.

192. A check on this differencing was to set down the complements of the first values in each group of tape 190 and to add to them the second values in each group. This is done in tape 192, and the total, marked  $\oplus$ , agrees with that in tape 191.

193. In equation (48) on page 349 the denominator for the value of  $n$  is

$$\log(115-x) - \log[115-(x+5)].$$

Since the rates of mortality used in this computation are for ages 94 to 103, it is necessary to find the logarithms of  $(115-x)$  from  $x=94$  to  $x=103$ , or of 21 to 12, both inclusive. The mantissas of these logarithms are shown consecutively on page 2 of the logarithm tables. In actual practice these logarithms, together with a number of others, and their quinquennial differences were copied on sample sheets which outlined these computations, so that the computer could use them in working out values for different tables without having to recompute them each time. However, for the convenience of the reader the work in tape 193 and tape 194 is shown here. In subtracting no attention need be given the characteristic of these logarithms, since it is either 1 or zero and disappears in the process of subtraction. The differences,  $\log 21 - \log 16$ ,  $\log 20 - \log 15$ , and so on, are set down in tape 193 and their total taken.

194. Then the logarithms of  $(115-94)$ , or 21, to  $(115-113)$ , or 2, are copied down in tape 194, subtotals being taken after each fifth value. The subtotals and totals are for convenience in checking.

195. Since the sum of the differences shown in tape 193 is the sum of the logarithms of the differences from  $(115-94)$ , or 21, to  $(115-98)$ , or 17, less the sum of the logarithms of the differences from  $(115-99)$ , or 16, to  $(115-103)$ , or 12, a check on the differencing in tape 193 is made by repeating the first subtotal in tape 194 twice and adding to it the complement of the second subtotal. The total, marked  $\oplus$ , is the same as that shown in tape 193.

196. Then, according to the equation (48) on page 349, the five different values for  $n$  are the five different quotients obtained by dividing each number in tape 191 by the corresponding number in tape 193. These were computed to the nearest eighth decimal place and set down in tape 196 as  $n_x$ , and a total taken.

197. Equations (49) on page 349, when  $x$  is substituted for  $b$  and 115 for  $M$ , become

$$\log \log a = \log(-\log q_x) - n \log(115-x) \quad (84)$$

$$\text{and} \quad \log \log a = \log(-\log q_{x+5}) - n \log(115-x-5).$$

In order to check the work thus far,  $\log \log a$  was determined from both equations. The first term on the right of each equation is negative, while the second is positive. Hence the remainder, or  $\log \log a$ ,

CALCULATION OF THE LIFE TABLE FOR MALES IN THE STATE OF NEW YORK: 1910  
 PHOTOGRAPHS OF ADDING MACHINE TAPES USED IN CONNECTION WITH NUMERICAL COMPUTATIONS

-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

is negative. The first value for  $n$  in tape 196 was set up on the calculating machine and multiplied by the first value in tape 194 and the product entered upon the left of the adding machine in tape 197. To it was added the first value of the first pair in tape 190. Then this same value of  $n$  is multiplied by the first value in the second group of tape 194, that is, the value for age 99, the product set upon the adding machine just below the first sum in tape 197, and to it is added the second value of the first pair in tape 190. These two sums are marked  $\oplus$  and they agree exactly, showing that the value of  $\log \log a$  from the first set of rates of mortality, those for ages 94 and 99, or  $\log \log a_{94}$ , is  $-1.48725954$ . The agreement of the two results is a check on the work for this value of  $\log \log a$ .

Then, on the right side of tape 197,  $\log \log a_{95}$  from the second set of  $q_x$ , those for ages 95 and 100, are computed in the same way; that is, the second value of  $n$  in tape 196 is set up on the calculating machine and then multiplied first by the second value in tape 194 and then by the second value in the second group. As the products were obtained they were set upon the adding machine and to them were added, respectively, the first and second values in the second pair of tape 190, giving the sum marked  $\oplus$ . Hence the value of  $\log \log a$  from this second set of values, or  $\log \log a_{95}$ , is  $-1.32641219$ . Then  $\log \log a_{96}$  was determined on the left of tape 197 from the third set of values, and so on. The values of  $\log \log a_{98}$  from the last set of values, marked  $\oplus$ , differ by unity in the last figure; however, this is not due to an error in the work, but only to the cutting off of fractions. The first value of a set was always used under such circumstances.

198. The five values for  $\log \log a_x$  are copied down in tape 198 from tape 197 and a total taken.

199. Twice the total in tape 198 was set up and repeated five times, giving as total ten times that in tape 198, as indicated by the mark  $\oplus$ . This gives the average value of the five values of  $\log \log a$  as  $-1.72618292$ .

200. To  $1.72618292$  is added its complement, or  $8.27381708$ , showing that when the mantissa is positive, or  $.27381708$ , the characteristic is 998 on the tape, or 2. or 8. as the characteristic is usually written. This complement is designated  $\overline{\log \log a}$ .

201. Twice the sum in tape 196 is set down and repeated five times, giving a total ten times that in tape 196, as indicated by the mark  $\oplus$ . This shows that the average value of  $n_x$  is  $1.10185038$  when taken to the nearest eighth decimal place, and is designated by  $\bar{n}$ .

202. After the Wittstein constants have been determined, the smoothed rates of mortality are computed from the formula

$$\log (-\log q_x) = \log \log a + \bar{n} \log (115 - x). \quad (85)$$

$\bar{n}$  was set up on the calculating machine, multiplied by the first value in tape 194, and the product to the nearest eighth decimal place entered upon the left

side of the adding machine in tape 202. The mantissa of  $\log \log a$  was added to this. The product of  $\bar{n}$  by the second value in tape 194 was set up four spaces below it on the right side, and the mantissa of  $\log \log a$  was added to it also. The product of  $\bar{n}$  by the third value in tape 194 was set up immediately below this on the left side, and so on.

203. As a check on this work the sums obtained in tape 202 were added. Then below this the product of  $\bar{n}$  times the sum of the  $(115 - x)$  in tape 194, taken to the nearest eighth decimal place, was set up on the adding machine and to it was added 21 times  $\log \log a$ , that is,  $.27381708$  plus 20 times  $.27381708$ . The total agrees with that obtained just above, as indicated by the mark  $\oplus$ .

204. Since only the mantissa of  $\log \log a$  was added in tape 202, the characteristic, or  $-2$ , had to be subtracted mentally. As the integral parts of the sums in tape 202 are either 1 or 0, the characteristic of the log  $(-\log q_x)$  is either  $-1$  or  $-2$ , respectively; that is, the antilogarithms,  $-\log q_x$ , will begin in the first or second decimal place, respectively. They were estimated to the nearest seventh decimal place by interpolation, this work being done with pen and ink, in tape 202. It was ordinarily worked in pencil, but is here shown in ink.

From the values of  $\log (-\log q_x)$  shown in tape 202,  $-\log q_x$  is a positive fraction; hence  $\log q_x$  is a negative fraction, or  $-1$  plus the complement of that fraction, the complement being the mantissa of  $\log q_x$ . In tape 204 the characteristic  $-1$  is not shown, but the antilogarithms of the logarithms in tape 202 are set down to five places and then the other two added by interpolation. This sum is then read through the glass at the base of the machine, its complement added, and a total struck. This complement, of course, is  $\log q_x$ . The machine was split between banks 7-8 and 10-11 and two consecutive antilogarithms and their complements set up together.

205. The antilogarithms of the logarithms in tape 204,  $10^6 q_x$ , were entered on the right of tape 205, the sixth figure being interpolated on tape 204. On the left of tape 205 are entered the  $10^6 p_x$ . The sum of the  $10^6 q_x$  and  $10^6 p_x$  gives 22, the number of items. Attached to the right of tape 205 is another tape, upon the middle of which are copied the  $10^6 q_x$  from tape 186 and on the right  $10^6 q_x$  from tape 173, beginning with age 85. Every fifth age, that is, 85, 90, 95, and so on, is entered on the left of this tape. These three tables of rates of mortality are set here side by side to compare them and to select the rates of mortality which are to be smoothed for the final table by Spencer's 21-term formula. In actual practice the three tapes 205, 186, and 173 can be pinned together while making this comparison. In making this selection three points were kept in mind:

(a) As many as possible of the rates from tape 173 were selected, since it seems desirable to extend the osculatory process just as far as the rates would appear to warrant such extension.

CALCULATION OF THE LIFE TABLE FOR MALES IN THE STATE OF NEW YORK: 1910  
PHOTOGRAPHS OF ADDING MACHINE TAPES USED IN CONNECTION WITH NUMERICAL COMPUTATIONS

[illegible]

(b) As few as possible of the rates of mortality from tape 205 were selected, because these rates depend less upon the actual data and more upon an artificial formula than do those in tapes 173 and 186.

(c) The rates of mortality selected should have about equal weight in determining the smoothed values. Those selected, therefore, should form a fairly smooth table, since values that do not fit in smoothly with the rest of the table would have more than their share of influence upon the smoothed values. The ones selected in this case were from tape 173 through age 93; from tape 186, age 94 through age 99; from tape 205, age 100 through age 115. The tables from tapes 186 and 205 are very close together from ages 96 to 99, but between ages 100 and 101 there is a rough place in tape 186: hence its values were used no further than age 99.

**RATES OF MORTALITY AT OLDER AGES SMOOTHED BY SPENCER'S 21-TERM FORMULA.**

206. To make certain of a smooth junction between the rates of mortality in tape 173 and the smoothed table, it was found best to extend the latter values as far back as age 80. Hence the rates of mortality in tape 173 from age 70 through age 93 are copied in tape 206; in tape 186, from age 94 through age 99; in tape 205, from age 100 through age 115. For purposes of checking, subtotals were taken after each fifth value and a total taken at the end.

207. Equation (50), page 350, for this smoothing process calls for division by 350, or by  $5 \times 7 \times 10$ . In order to decrease the size of the numbers used, the division by 7 was performed first, either mentally or by aid of Crelle's Rechentafeln, opened to the page showing multiples of 7. The quotient to the nearest integer is set down in the middle of tape 207 and the remainder is set down on the right side, the machine being split between banks 14-15. When the remainder was 4, 5, or 6 the quotient on the left was increased by unity and 997, 998, or 999, respectively, set down in the remainder column, since in this case the remainder was considered negative. For purposes of checking, subtotals were taken after each fifth value and a total taken at the end. For convenience in reference these quotients were designated by  $u_x$ . The ages are entered on the left of tape 207.

208. The check on the above work is to repeat the total of the quotients in tape 207 seven times and to add to it the sum of the remainders. As indicated by the mark  $\textcircled{20}$ , the total here is the same as in tape 206.

When one is using Crelle's Rechentafeln it is easy to check up the work after each subtotal. For instance, if a check is desired upon the third subtotal of tape 207

the product of  $7 \times 249,000$  is 1,743,000,  
the product of  $7 \times 764$  is 5,348,  
the sum of the remainders is 10;

then the sum is 1,748,358,

which is the third subtotal in tape 206.

209. The next step was to obtain the operand in equation (50) on page 350, that is,

$$U_x = -u_{x-3} + u_{x-1} + 2u_x + u_{x+1} - u_{x+3},$$

where the operand is designated by  $U_x$ . It was found convenient to determine two consecutive values of  $U$  at the same time, so the machine was split between banks 8, 9, and 10. By comparing Table 134 with the values in tape 207 it is easy to devise a mechanical method of determining these values of  $U$  on the adding machine.

**Table 134**

| DERIVATION OF THE OPERAND IN SPENCER'S 21-TERM FORMULA FOR AGES 73 TO 76. |          |          |          |          |          |          |                   |
|---------------------------------------------------------------------------|----------|----------|----------|----------|----------|----------|-------------------|
|                                                                           | $U_{73}$ | $U_{74}$ | $U_{75}$ | $U_{76}$ | $U_{73}$ | $U_{74}$ | $U_{75}$ $U_{76}$ |
| $u_{x-3}$                                                                 | 9811     | 10296    | 11037    | 11840    | $a$      | $b$      | $c$ $d$           |
| $u_{x-1}$                                                                 | 11037    | 11840    | 12732    | 13737    | $c$      | $d$      | $e$ $f$           |
| $u_x$                                                                     | 11840    | 12732    | 13737    | 14793    | $d$      | $e$      | $f$ $g$           |
| $u_{x+1}$                                                                 | 12732    | 13737    | 14793    | 15857    | $e$      | $f$      | $g$ $h$           |
| $u_{x+3}$                                                                 | 14793    | 15857    | 16955    | 18211    | $g$      | $h$      | $i$ $j$           |

The values of  $u$  which are used in calculating the values of  $U_{73}$ ,  $U_{74}$ ,  $U_{75}$ , and  $U_{76}$  are copied on the left side of Table 134 from tape 207, and the symbols which are used in the formula for  $U_x$  appear in the first column. If the first ten values in tape 207 be designated by  $a$ ,  $b$ ,  $c$ , and so on, to  $i$ , and  $j$ , then the values of  $u$  entering into the calculation of  $U_{73}$ ,  $U_{74}$ ,  $U_{75}$ , and  $U_{76}$  are shown in the four columns on the right of the table. When the values for the first two  $U$ 's were calculated simultaneously, the value  $a$  would be set down on the left of the machine and  $b$  on the right; then beneath them  $c$  on the left and  $d$  on the right. Here a break occurs,  $d$  being set down again, this time on the left, while  $e$  is put on the right and the two repeated twice by means of the repeat key. Then setting down  $e$  again, this time on the left,  $f$  is entered on the right; then  $g$  on the left and  $h$  on the right.

Then starting the calculation of the next two values of  $U$ , that is,  $U_{75}$  and  $U_{76}$ , the first line is  $c$  and  $d$ , which is the second line in the calculation of the pair before. The same process is repeated in the calculation of  $U_{75}$  and  $U_{76}$  as in the calculation of  $U_{73}$  and  $U_{74}$ . One thing which must be remembered, however, is that the complements of the first and last line of values must be set up instead of the values themselves.

210. For convenience in reference and checking, the values of  $U_x$  are copied, taking subtotals after the same ages as in tape 207. Hence there are only two values in the first group and only three in the last. From the formula for  $U_x$  it will be noted that, with the exception of the first six and the last six values, all the values in tape 207 are added four times and subtracted twice, so that each enters twice in the sum of

all the  $U$ 's. Also, since the formula is symmetrical, values at the same distance from the beginning and end of tape 207 will be added and subtracted the same number of times. Hence the first two and the last two values are each subtracted once. The third values from the ends are each added once and subtracted once. The fourth values from the ends are each added three times and subtracted once. The fifth and sixth values from the ends are each added four times and subtracted once. These statements can readily be checked up by writing down the calculation of the next pair of  $U$ 's in Table 134, page 398, that is, the  $U$ 's for ages 77 and 78, and then studying the letters that enter into the calculation of these three pairs.

211. From the above statements it is seen that

$$2 \sum_{x=70}^{x=115} u_x = \sum_{x=73}^{x=112} U_x + 3(u_{70} + u_{71} + u_{114} + u_{115}) + 2(u_{72} + u_{113}) - (u_{74} + u_{75} + u_{110} + u_{111}). \quad (86)$$

Hence in tape 211 the first two values in tape 207 are repeated three times on the left, and opposite them on the right the last two quantities are repeated in the same way. Then the values third from the ends are repeated twice, the one near the beginning on the left and the other on the right. After this the complements of the fifth and sixth values are set down, those near the beginning on the left and those near the end on the right. Their totals are then added to the total of tape 210, and the sum is found to equal twice the total of tape 207, as indicated by the mark  $\otimes$ .

If the totals marked  $\otimes$  do not agree, the first total on the left of tape 211 is convenient to use in locating the error, for a check similar to that in tape 211 can be made on any part of tape 210. In locating an error it is well to check the middle of the column first, say the subtotal after age 94. The operation on the first six values in tape 207 would be the same, giving the total 55,326, but the value for age 97 instead of that for age 115 would be the last value in tape 207 to be used. Hence the operation would be as follows, the addition of the first four numbers on the left being to

determine  $\sum_{x=70}^{x=97} u_x$  in place of  $\sum_{x=70}^{x=115} u_x$ , or 2,432,099, which were used in tape 211:

|         |          |
|---------|----------|
| 605744  | 49477    |
|         | 49477    |
| 49477   | 49477    |
|         | 47789    |
|         | 47789    |
| 47789   | 47789    |
|         | 45846    |
| 45846   | 45846    |
|         | 99958256 |
|         | 99961835 |
| 748856  | 303581s  |
| 748856  | 55326    |
|         | 1138805  |
| 1497712 | 1497712* |

If these totals do not agree there is an error before age 95, and some subtotal midway between the beginning of the column and age 95 should be checked, say age 85. If the totals do agree the error occurs after age 94, and the subtotal before age 105 should be checked.

212. The formula for this smoothing process calls for the addition of the operand twice in groups of fives and once in groups of sevens. The first addition of the operand  $U$  was that in groups of sevens, and the sums were designated by  $v$ . Since the first value in tape 210 is for age 73, the first  $v$  would be for age 76, and its value is given by the second subtotal in tape 210, that is, 203,477. Starting tape 212 with this value,  $U_{73}$  was subtracted and  $U_{80}$  added and a subtotal taken to obtain  $v_{77}$ . This process was repeated to the end of tape 210. To save space the machine was split between banks 11-12 and 8-9 and the first half of the additions performed on the left of the tape; then the paper was rolled back and the last half of the addition performed on the right.

213. The work in tape 212 was checked by adding the last five values in tape 210 independently, that is, by subtracting the next to the last subtotal in tape 210, or 2,313,600, and 163,377 from the total 3,937,261. As indicated by the mark  $\otimes$ , the total in tape 213 agrees with that in tape 212.

214. For convenience in reference and checking, the  $v$ 's obtained in tape 212 are copied in tape 214, a subtotal being taken after each fifth value and a total at the end.

215. The total in tape 214 would not equal seven times the total of tape 210. In order to bring the total of tape 214 up to the latter sum there must be added to it six times the first and last terms in tape 210, five times the second from each end, four times the third from each end, and so on until the ones sixth from the ends have been added. The first term in tape 210 is set down on the left of tape 215, and on the right the last term, and then they are repeated six times. Just beneath them are set down the values in tape 210 second from the beginning and end, respectively, and they are repeated five times, and so on until the values sixth from the ends of tape 210 are added. On the right of tape 215 these totals are then added to the total of tape 214, while on the left the total of tape 210 is repeated seven times. The two sums marked  $\otimes$  agree.

If the sums do not agree, the approximate location of the error may be found by checking some of the subtotals in tape 214, say the one after age 95. The values at the beginning of tape 210 would be operated upon in the same way and the total, 553,240, on the left of tape 215 would be used, but the value for age 98 instead of that for age 112 in tape 210 would be used. Hence the operation would be performed as

When one has the operation well in mind it can be shortened by reading the subtotal 1,520,599, or  $\sum_{x=73}^{x=98} U_x$ , through the glass at the base of the machine and setting it up on the right. Then 1,138,805 was subtracted, and resulting subtotal 381,794, or  $\sum_{x=95}^{x=98} U_x$ , read through the glass, was repeated twice.

216. In order to decrease the size of the operand again, another of the three divisions is performed mentally, that is, the division by five is made by multiplying the values in tape 214 by two mentally. The product, with the exception of the last figure, is entered in the middle of tape 216 and the last figure on the right, the machine being split between banks 6-7 and 14-15. Ages are entered on the left. However, when the last figure of the product was 6 or 8, 996 and 998, respectively, were set down on the right, and the corresponding integral part in the middle was increased by unity. Subtotals were taken after each fifth value and a total at the end for the purpose of checking.

217. As a check on this work the sum of the integers on the left of tape 216 was added to the sum of the decimals on the right and the total repeated five times. As indicated by the mark @, this sum agrees with ten times the total of tape 214.

218. The next addition was that of the quantities in tape 216 in groups of five as those in tape 210 were added in groups of seven in tape 212. Beginning with the first subtotal in tape 216, that is, 236,915, this addition is performed in tape 218. The sums of the groups of five were designated by V.

219. As before, the check on this work was to add the last five quantities in tape 216 independently, which sum in this case equals 230,270 plus the complement of the last subtotal in tape 216, or 3,385,682, plus the total 4,457,111. As indicated by the mark @, this sum agrees with the total of tape 218.

220. For convenience in reference and checking, the V's in tape 218 were copied in tape 220, subtotals being taken after each five and a total taken at the end.

221. As before, this work was checked by adding the total of tape 220 to four times the first and last terms of tape 216, three times the second and next to last terms, and so on to the fourth terms from the end. The agreement of this sum with five times the total of tape 216 is indicated by the mark @.

222-225. By processes identical to those in tapes 218 to 221 the values in tape 220 were added in groups of five, checked, copied, and checked again in tapes 222 to 225. Since this completes all the processes required by the smoothing formula or equation (50) on page 350, except the division by 10, the values in tape 224 are the smoothed values of  $10^7 q_x$  from age 80 to age 105.

226. These values were reduced to  $10^6 q_x$  by setting down the first six figures in each value on the right and the seventh figure on the left. When the seventh figure was 5 or over, it was preceded by 9 and the sixth figure on the right increased by unity. The  $10^6 p_x$  was entered in the central column. The sum of the  $p_x$  and  $q_x$  columns should be an integer equal to the number of rates of mortality entered.

227. The reducing of the  $10^7 q_x$  and the copying of the  $10^6 q_x$  in tape 226 were checked by adding the sum of its integral parts, and the mark @ signifies that the totals in tape 227 and tape 224 agree.

228. An inspection of the rates of mortality in tapes 173, 226, and 205 led to the selection of ages 79-80 as the junction point between the first pair and 104-105 as the junction point between the second pair. Then the values of the rates of mortality in the final table from ages 75 to 109 were entered in tape 228 on the left, their first differences in the middle and second differences on the right, in order to insure that no violent breaks occur in these differences at the junction point. Horizontal lines mark the places of junction.

PHOTOGRAPHS OF ADDING MACHINE TAPES USED IN CONNECTION WITH NUMERICAL COMPUTATIONS

[illegible]

## CALCULATION OF LIFE TABLE FUNCTIONS.

229. All the rates of mortality for the life tables being selected, the next step was to collect and base a life table on their complements, or  $p_x$ . These values are given on the right of tape 146 for ages by months under 1 year and by years from 1 to 4; on the right of tape 173 for ages 5 to 79; in the middle of tape 226 from 80 to 104; and on the left of tape 205 from 105 to 115.

The radix of the life table was taken as 100,000 at age 0. From the value of  $p_x$  mentioned above the values of  $l_x$  were determined to the nearest fourth decimal according to equation (51). In tapes 229, 231, and 232 additions of values of  $l_x$ , required by equations (52) to (55) on pages 351 and 352, are made as a first step in obtaining tape 233 for ages by months under 1 year, tape 235 for ages 1 to 4 years, and tape 236 for ages 5 to 112. The machine is split between banks 14-15 and the age of the  $l_x$  entered opposite it on the left; this age appears again in the total where it represents the age of the  $L_x$  which will be derived from this total. Time can be saved and accuracy increased by entering these values of  $l_x$ , as computed, upon the adding machine in tapes 229, 230, and 232 instead of making a separate copy of them.

Following equation (54) on page 351, 100,000.0000 is set up on the adding machine and 95,264.8 added to it three times with the repeat key, and a total taken. Then, in accordance with equation (55), just beneath this total, 95,264.8000 is set up again with 1 in bank 15 to indicate the age of 95,264.8000. Then  $p_1^{(12)}$ , or .986,500, is set up on the computing machine and multiplied by 95,264.8, and the product, 93,978.7252, taken to the nearest fourth decimal, is entered on the adding machine beneath the 95,264.8000, and a total taken. The 93,978.7252 is then set up on the adding machine just below this total, with 2 in bank 15, and also upon the computing machine, where it is multiplied by  $p_2^{(12)}$ , and the process repeated. Only the work for a few ages is set down here.

230. When the equations (52) on page 351 are added the following is obtained:

$$100 \sum_{x=1}^{x=4} L_x = 41l_1 + 106l_2 + 101l_3 + 100l_4 + 52l_5. \quad (87)$$

Following equation (87),  $l_1$  was set up in unit's place in tape 230 and then repeated four times in ten's place;  $l_2$  was set up in unit's place, again in hundred's place, and one-half of it in ten's place;  $l_3$  was set up in unit's place and again in hundred's place;  $l_4$  was set up in hundred's place;  $l_5$  was repeated twice in unit's place and one-half of it set up in hundred's place. The final sum is used as a check on the work in tapes 231 and 235.

On the left the age is set opposite the entry of each  $l_x$  in unit's place, except that 4 is set opposite  $100l_4$ .

231. In tape 231 the  $l_x$  added in tape 230 are again added to obtain the values for each of the four equations (52) on page 351. Hence  $l_1$  is set once in unit's place and repeated four times in ten's place, and to this is added  $l_2$  once in ten's place, the complement of  $l_2$  in unit's place, one-half of  $l_2$  in hundred's place, and a total taken. Then one-half of  $l_2$  is set up in hundred's place, the complement of  $l_2$  is repeated three times in unit's place, and to this is added  $l_3$  repeated three times in unit's place, and one-half of  $l_3$  added in hundred's place, and a total taken. The complement of  $l_3$  is repeated twice in unit's place, one-half of  $l_3$  is set up in hundred's place, and to this is added  $l_4$  repeated twice in unit's place, and one-half of it in hundred's place. In the same way the complement of  $l_4$  is repeated twice in unit's place, one-half of  $l_4$  is added in hundred's place, then  $l_5$  is repeated twice in unit's place, and one-half of it added in hundred's place. These four totals in tape 231 are  $10^5 L_x$  for ages 1 to 4 years.

232. Beginning with age 5,  $l_x$  is added to  $l_{x+1}$ , according to equation (53), the age appearing in banks 16-17 opposite  $l_x$  and again in the total, from which  $L_x$  will be derived. The work for only a few ages at the beginning and for ages 80 to 115, the latter being used in tapes 243 and 245, is all that is shown here. Age 112 is the last one to appear, since  $l_x$  for ages higher is less than .00005.

233. According to equations (54) and (55) on pages 351 and 352, the first sum in tape 229 should be divided by 48 to obtain  $L_0^{(12)}$ , and the other sums by 24 to obtain the remaining  $L_x^{(12)}$ . These quotients are set down to the nearest fourth decimal place in tape 233, a space being made between the sixth and seventh values, and a subtotal taken at the end. This subtotal was set up once in unit's place, once in ten's place, and a total taken, which is twelve times the sum of the  $L_x^{(12)}$ . This total is for checking purposes.

234. If the values of  $x$  from 1 to 11 months be substituted in equation (55) on page 352, eleven equations are obtained. If these eleven equations and equation (54) on page 351 be each multiplied by 12 and added together, the following equation is obtained:

$$\begin{aligned} 12 \sum_{x=0}^{x=11} L_x^{(12)} &= (l_0^{(12)} + 3l_1^{(12)})/4 + (l_1^{(12)} + l_2^{(12)})/2 + \\ &\quad (l_2^{(12)} + l_3^{(12)})/2 + \dots + (l_{11}^{(12)} + l_{12}^{(12)})/2 \\ &= l_0^{(12)}/4 + l_1^{(12)}/4 + l_1^{(12)} + l_2^{(12)} + l_3^{(12)} + \\ &\quad \dots + l_{11}^{(12)} + l_{12}^{(12)}/2. \end{aligned} \quad (88)$$

Accordingly, one-fourth of  $l_0^{(12)}$  and  $l_{11}^{(12)}$ , 25,000.0000 and 23,816.2000, respectively, are set down in tape 234, followed by the other  $l_x^{(12)}$ , beginning with  $l_1^{(12)}$  and ending with one-half of  $l_{11}$ , the survivors to one year. As indicated by the mark @, the totals in

[illegible]

tapes 233 and 234 agree, thus checking the results for  $L_x^{(12)}$  by months under 1 year of age.

235. The totals obtained in tape 231, or  $L_x$ , from ages 1 to 4 years are added in tape 235, and, as indicated by the mark @, the totals in tapes 235 and 230 agree, thus checking the work on these values of  $L_x$ .

236. Then the totals in tape 232 are divided mentally by two and the results entered in tape 236 to the nearest integer; these are repeated twice by the repeat key, and a total taken. However, beginning with age 80 and continuing to age 112, the quotient to the nearest fourth decimal was entered in tape 236, in order to obtain the values in tape 243 and the measure of vitality according to sections 242 and 245. Only ages 5 and 6, 80 and 81, and 103 to 112 are shown here. The other values between ages 6 and 80 can be obtained from the life table on page 162, and those between ages 81 and 103 can be obtained by taking one-half of the sum in tape 232. For the benefit of the reader the ages are indicated in banks 16-17. In practice the sums can be marked off in groups of five with a pencil.

237. The values for  $l_x$  in tapes 229, 230, and 232 were copied in column 2 of the life table on page 162 to the nearest integer, so that age 105-106 is the last age interval appearing in the life table.

238. These  $l_x$  in column 2 of the life table are then differenced and the differences set down in column 3. These, of course, are the  $d_x$ .

239.  $L_x$ , to the nearest integer, from tapes 233, 235, and 236, is copied in column 6 of the life table on page 162, the last age interval being 105-106. It is well to check this copying of the  $L_x$ , since any error in them will destroy the value of the next work.

240. The  $d_x$ , section 238, are checked on tape 240 by starting with  $l_{106}$ , or zero, and adding to it  $d_{105}$ , then  $d_{104}$ ,  $d_{103}$ , and so on, comparing the total, seen through the glass at the base of the machine, after each addition with the corresponding  $l_x$ . Of course, the fact that the sum of the  $d_x$  is 100,000 is a check, but compensating errors would not change the total. To render this work more compact, the machine was split between banks 10-11, the first part of the addition performed in banks 10 to 17, and a subtotal taken after the addition of deaths in age interval 45-46. Then the tape was rolled back, this subtotal set up in banks 1 to 5, and the remaining  $d_x$  added.

To check the deaths by months under 1 year, the survivors to age 1 year, 87,287, is set up on the adding machine,  $d_{11}^{(12)}$  added, then  $d_{10}^{(12)}$ , and so on, the total after each addition being compared with the corresponding  $l_x^{(12)}$ .

241. Following equation (56) on page 352, the values of  $T_x$  were obtained by summing the values of  $L_x$  in column 6 of the life table, page 162, beginning with age 105-106, and taking a subtotal after each addition, the subtotal being  $T_x$ . The final total, or  $T_0$ , was then compared with that obtained by the operator who duplicated this work.

In order to condense this addition the machine was split between banks 9-10, the first part of the addition through age interval 45-46 performed on the left of the tape, and then a subtotal taken. The tape was then rolled back and this subtotal set up in banks 1 to 7 and the rest of the addition performed.

242. According to equations (58) on page 352,  $\lambda_x^{(12)} = 12L_x^{(12)}/d_x^{(12)}$  and  $\lambda_x = L_x/d_x$ , where  $L_x$  and  $d_x$  are taken to the nearest integer, that is, from columns 7 and 3, respectively, of the life table on page 162, up to age 80; but from that age to age 105,  $L_x$  to four places of decimals was obtained from the last part of tape 236 and the  $d_x$  to four places of decimals was obtained from tape 242.

Referring back to tape 232, the values of  $l_x$  to the nearest fourth decimal are grouped, each two consecutive ages together, the age of the younger value appearing opposite it on the left. These values were differenced mentally from age 80 to age 105 and the results set down in tape 242. At the end a subtotal was taken and  $l_{106}$  added to it, giving  $l_{80}$  as the total, as indicated by the mark @, which is only a partial check on the work, since compensating errors could not be detected in this way. However, since signs were not considered in this differencing, the usual way of checking could not be used as in tapes 149 to 152, and to have written these  $d_x$  in an order reverse to that in tape 232 would have caused confusion in performing the divisions mentioned above.

243. From equation (57) on page 352,  $\theta_x = T_x/l_x$ .  $T_x$  and  $l_x$  are taken to the nearest integer, or from columns 8 and 2, respectively, of the life table on page 162, up to age 80, but from that age on to the end of the life table, age 105,  $T_x$  to four decimal places is taken from tape 243, while  $l_x$  to four decimal places is taken from tape 232.

In tape 243 the  $L_x$  are added to four decimal places, beginning with age 112 in tape 236 and ending with age 80, a subtotal being taken after each addition beginning with age 105. This gives the  $T_x$  mentioned just above. The mark @ indicates that the results for  $T_{80}$  in tapes 243 and 241 practically agree.

244. These subtotals in tape 241, or  $T_x$ , were then copied in column 8 of the life table on page 162.

245. The divisions indicated in the first paragraph of section 242 were made and the quotients to the nearest second decimal set down in column 7 of the life table on page 162.

246. Then the divisions indicated in the first paragraph of section 243 are made and the quotients to the nearest second decimal set down in column 5 of the life table on page 162.

247. According to equation (59) on page 352, the values of  $1000l_x/T_x$  were obtained by multiplying the reciprocals of the values in column 5 of the life table on page 162 by 1,000 and entering the results in column 9 of the life table to the nearest second decimal. Barlow's Table of Reciprocals was used.

## 407

[illegible]

248. From tapes 146, 173, 226, and 205 the values of  $1,000q_x$  were copied to the nearest second decimal in column 4 of the life table on page 162, according to the ages shown in columns 17-22, line 56, Table 135, page 419.

249. Then the duplicate life table values were carefully compared.

**CALCULATION OF RATES OF MORTALITY JOINING THOSE UNDER AGE 5 WITH THOSE BY OSCULATORY INTERPOLATION, FOR WHITE FEMALES IN CITIES OF THE ORIGINAL REGISTRATION STATES, 1901.**

250. Beginning with the left side of Table 118 on page 352, the values for the first four columns are set down in order in tape 250. As will be seen from columns 9 and 10, line 29, of Table 135 on page 416,  $10^6q_3$  was taken from tape 146 and  $10^6q_{13}$  and  $10^6q_{14}$  from tape 173 of the calculation of rates of mortality for white females in cities of the original registration states, 1901, which, of course, are not shown in the preceding computations.

251. The next two columns in Table 118, page 352, are entered in tape 251, the multiplications and subtractions being performed mentally. A check on this work is obtained by adding the fractional part of the sum of  $10^6(2-q_x)$  to the sum of  $2(10^6q_x)$ , the total being the sum of  $10^6q_x$  in tape 250, as indicated by the mark @. The ages are entered in banks 16-17, the machine being split between banks 8-9 and 15-16.

252. The values of  $m_x = 2q_x/(2-q_x)$ , to the nearest twelfth decimal place, were entered on the right of tape 252, being obtained from the values in tape 251. The object in taking so many decimal places at this and several other points in these calculations was to relieve the operator of any consideration of the problem of the minimum number of places necessary to insure a final check to a specified number of decimal places on the quantities or values sought or to be calculated. In banks 16-17 the ages are entered and the products of  $u_x v_x$ , obtained mentally from their values in tape 250, are copied in ink to the right of them.

253. The values of  $U_x$ , determined from the values in tape 252, according to the formula  $U_x = m_x/u_x v_x$  in Table 118, page 352, were entered to the nearest thirteenth decimal place in tape 253. The total is  $10^{13}U$ . The ages are entered in banks 16-17, and between them and the  $U_x$  the factors of  $U_x$  are copied from the last column of Table 118.

254. The sum of the products of the corresponding values in the two columns of tape 253 was obtained by entering  $U_3$  once in unit's place and twice in ten's place,  $U_{13}$  once in unit's place and once in ten's place, and  $U_{14}$  once in ten's place, the total being  $10^{13}V$ , according to the last column in Table 118.

255. The first four columns in Table 119, page 353, are entered in tape 255. Where a number of tables are to be computed from the values for the same ages of  $x$ , these four columns, together with the first three in tape 250 and those in ink in tapes 252 and 253,

were entered in a table used to outline the work, and it was not necessary that they be entered upon the tape.

256. The deaths used in these computations are for the three-year period 1900-1902, and the population at the middle of the period would be as of July 1, 1901. In banks 10 to 15 were entered the population aged 3 on July 1, 1910, and in banks 1 to 6 the population aged 4 at this date. These were taken from column 2 of Table 148 on page 439. To these were added the complements of the population aged 3 and 4, respectively, on July 1, 1900, and then ten times the populations aged 3 and 4, respectively, on July 1, 1900, obtained from column 7 of Table 171 on page 462. The sum is ten times the estimated populations aged 3 and 4, respectively, on July 1, 1901. According to columns 3 and 6, line 29, Table 135, on page 416,  $P_3$  and  $P_4$  are taken from the original statistics for both 1900 and 1910, but  $L_3$  to  $L_{14}$  are taken from tape 161 for white females in cities of the original registration states, 1901. In other words, the estimation of population as of July 1, 1901, was made between population in quinquennial age groups from Tables 148 and 171; then the interpolation into population by single years of age was made.

257. The last four columns in Table 119 on page 353 are entered in tape 257 with the order of the last three columns reversed in order to put two columns side by side on the tape. The column of  $L_x$  was obtained from tape 256, which shows here only  $P_x$  for the two ages 3 and 4.

Since the deaths upon which this work is based are for a three-year period, the populations had to be multiplied by three. Hence the subtotals of each column were repeated twice, so that the final total is three times the sum of the column; that is, the final totals are  $32L_x$ ,  $32y^3L_x$ ,  $32y^2L_x$ , and  $32yL_x$ .

258. Substituting the values of  $e$  and  $f$  from tape 253 in equation (64) on page 352, the equation for  $K$  becomes

$$K = \frac{M - U\Sigma y^2L_x + V\Sigma yL_x - 110U_3\Sigma L_x}{\Sigma y^3L_x - 21\Sigma y^2L_x + 110\Sigma yL_x}. \quad (89)$$

At the beginning of tape 258 the deaths for ages 3, 4, 5-9, and 10-14, taken from column 11 of Table 171 on page 462, are added to obtain  $M$ . A subtotal is taken, and to this are added the other quantities in the numerator of the above equation. The decimal point is between banks 6 and 7. The values of  $U$  and  $U_3$  were obtained from tape 253,  $V$  from tape 254, and the  $32L_x$ ,  $32yL_x$ ,  $32y^2L_x$ , and  $32y^3L_x$  from totals in tape 257. The three products were taken to the nearest sixth decimal place, as indicated by the vertical lines; the complements of the first and last products were entered. The machine was split between banks 13-14. It will be noted that the sum of these products is a negative number; hence after taking a subtotal the complement of this subtotal was added to it, thus showing that the sum of the four quantities in the numerator in the above equation for  $K$  is  $-2,475.529993$ .

REGRAUATION OF THE RATES OF MORTALITY OF WHITE FEMALES IN CITIES OF THE ORIGINAL  
REGISTRATION STATES, 1901, BETWEEN AGES 3 AND 13, TAPES 250-263, AND  
CALCULATION OF THE MEAN POPULATION OF WHITE FEMALES IN THE ORIGINAL REGISTRATION  
STATES FOR THE PERIOD 1901-1910, BEGINNING WITH TAPE 264

To obtain the denominator in this equation,  $3\Sigma y^2 L_x$  was added to the complement of 21 times  $3\Sigma y^2 L_x$  and 110 times  $3\Sigma y^2 L_x$ , the quantities being taken from tape 257. The products of the last two by 21 and 110, respectively, were obtained by addition in the same way as those in tape 254.

259. Substituting the values of  $e$  and  $f$  from tape 253 in equations (65) on page 353, these become

$$\begin{aligned}\delta m_3 &= U - V + 90K. \\ \delta^2 m_3 &= 2U - 36K. \\ \delta^3 m_3 &= 6K.\end{aligned}\quad (90)$$

These equations and the equations for  $K$  in section 258 should be entered upon the table outlining the work when the computations are based upon  $q_3$ ,  $q_{13}$ , and  $q_{14}$  and the populations and deaths between these ages.

In computing  $K$  and  $m_x$  and its leading unit differences, all of which except  $K$  were computed to thirteen decimal places, the machine was split between banks 13-14 and the decimal point considered as coming between these two banks. A vertical line indicates the decimal point.

The value of  $K$  to the nearest twelfth decimal place was found to be  $-.000007930489$  by dividing the first total in tape 258 by the second. Since it is negative, one hundred times its complement was entered in tape 259 and ten times its actual value, or ten times the complement of its complement, was added to obtain the  $90K$  needed in the first of the equations (90) just above. To this was then added the value of  $U$  from tape 253 and the complement of  $V$  from tape 254, the total being  $\delta m_3$ . The decimal point is indicated by the vertical line. In actual practice time will be saved by combining the two steps indicated in tapes 259 and 261.

260. To the value of  $K$  was added ten times  $\frac{1}{2}K$ , or  $5K$ , to obtain the constant third difference,  $\delta^3 m_3$ . A subtotal was taken and to it was added ten times one-half its value, or  $30K$ , to obtain the  $36K$  needed in the second equation above. Since this  $36K$  is to be subtracted, its complement is set up and repeated twice, once to clear the machine and the second time to enter it upon the machine. Then the value of  $U$  from tape 253 is repeated twice and a subtotal taken, which is  $\delta^2 m_3$ . To this subtotal the constant third difference,  $\delta^3 m_3$ , obtained above, is added nine times, a subtotal being taken after each addition and a total at the end. In this way  $\delta^2 m_x$  for  $x=3$  to  $x=12$  were obtained. The decimal point is indicated by the vertical line.

261. To  $\delta m_3$  from tape 259 were added the  $\delta^2 m_x$  in tape 260, a subtotal being taken after each addition and a total at the end. This gives  $\delta m_x$  for  $x=3$  to  $x=13$ . As in tapes 258 to 260, 262, and 263, the decimal point is indicated by a vertical line.

262. To  $m_3$  from tape 252 were added the  $\delta m_x$  from tape 261, a subtotal being taken after each addition to give the values of  $m_x$  from  $x=3$  to  $x=14$ . Since

$m_3$  is given only to the twelfth decimal place, it was moved one place to the left in adding it to the  $\delta m_3$  which are given to the thirteenth decimal place. A check on the work to this point is that  $m_{13}$  and  $m_{14}$  agree to the eleventh decimal place with those in tape 252, as indicated by the mark  $\oplus$ .

263. Another check on the work thus far is to multiply the  $m_x$  obtained in tape 262 by the  $L_x$  in tape 257 to obtain the expected deaths. According to the assumption in equation (63) on page 352, the sum of the expected deaths must equal the actual, or 18,951 from tape 258. Since the actual deaths were for three years, the sum of the expected deaths was repeated three times and the final sum is 18,950.97, since the  $L_x m_x$  were taken to the nearest second decimal place.

On the right of tape 263 are entered the  $10^6 q_x$  obtained from  $m_x$  in tape 262 by the formula

$$q_x = \frac{2m_x}{2 + m_x} \quad (91)$$

It was found convenient to compute the values in the two columns of tape 263 in the following order:  $m_x$  to the nearest ninth decimal place was set upon the computing machine as one factor, leaving space on the left so that 2 could be set up in unit's place. This  $m_x$  was then multiplied by  $L_x$  and the product entered upon the left of tape 263. Then this product and  $L_x$  were cleared from the machine, the  $m_x$  was multiplied by 2, and the 2 then cleared from the machine. The regulator was then switched to division, 2 set up in unit's place of the divisor, and the  $2m_x$  divided by  $2 + m_x$  to obtain the value of  $q_x$ . The values of  $q_3$ ,  $q_{13}$ , and  $q_{14}$  are the same as in tape 250.

#### CALCULATION OF MEAN POPULATION OF WHITE FEMALES IN THE ORIGINAL REGISTRATION STATES FOR THE PERIOD 1901-1910.

264. The total white female populations in the original registration states, enumerated on June 1, 1900, and April 15, 1910, were obtained from columns 2 and 3, respectively, of Table 174, page 465, and entered in tape 264 as  $P_{1910-June-1}$  and  $P_{1910-April-15}$ , respectively.

Their ratio,  $\frac{P_{1910-April-15}}{P_{1900-June-1}}$ ,  $r^{118.5/120}$ , carried to the nearest ninth significant figure, is entered just below. Beneath this is  $\log r^{118.5/120}$ , showing the three interpolations necessary when Bauschinger and Peters' eight-place logarithm table is used. This logarithm was divided by 118.5 and the quotient multiplied first by 120, the result being entered as  $\log r$ ; then the quotient was multiplied by seven, the result being entered as  $\log r^{7/120}$ . Space was left after these last two entries, and the computations necessary to obtain their antilogarithms are shown in ink.

$\log r$  was divided by .4342945 and the quotient set down on the machine as  $\lambda r$ . Beneath this is set down the value of  $r$  and of  $r^{7/120}$ , obtained from their logarithms. From these values,  $r^{7/120} (r-1)/\lambda r$  was obtained and entered as  $\alpha$ , according to equation (77)

REGRAUATION OF THE RATES OF MORTALITY OF WHITE FEMALES IN CITIES OF THE ORIGINAL REGISTRATION STATES, 1901, BETWEEN AGES 3 AND 13, TAPES 250-263, AND CALCULATION OF THE MEAN POPULATION OF WHITE FEMALES IN THE ORIGINAL REGISTRATION STATES FOR THE PERIOD 1901-1910, BEGINNING WITH TAPE 264

on page 354. Then the value of the constant  $\beta = (\alpha - 1)/(r^{118.5/120} - 1)$  from equation (76) on page 354 was set down.

265. Since the census report for June 1, 1900, does not show the populations by single years of age 100 years and over, these were estimated by assuming that the populations by single ages for these years in 1900 and 1910 were proportional to the total populations 100 years of age and over in 1900 and in 1910.

The machine was split between banks 3-4, 5-6, 10-11, and 14-15.

On the left of tape 265 the ages were entered; then the populations by single years of age 100 years and over in 1910, taken from column 8 of Table 174 on page 465, are added. Beneath this is shown the ratio of the population 100 years and over in 1900 to that in 1910. This ratio is carried to the nearest tenth significant figure to fill the ten-place computing machine used. The integral parts of the products of this ratio times the numbers under 1910 in tape 265 are entered in corresponding positions in banks 6-8, while the fractions are entered in banks 1-3 to the nearest second decimal. When the fraction was .50 or over it was preceded by 9 in bank 3 and the integral part was increased by unity. This kept the total sum of integral parts plus fractions almost exactly correct. When the sum of the fractions was .50 or over, this indicated that another integral should be increased by unity, and the one whose fraction was nearest to .50 was selected. In this case 10.46, the population for age 103, was changed in ink to 11 plus 9.46, the 9 serving to subtract .54 from the total of the fractions instead of the .46 being added to it. This reduced the difference between the sum of fractions less than .50 and the sum of increases made in the integers to zero. Then the sum of the integral part was changed from 157 to 158, which is the number of persons 100 years of age and over in 1900. Since the population for ages 103 and 104 were the same, the increase was added to the younger age.

266. The populations enumerated on June 1, 1900, and April 15, 1910, by single years of age are shown in columns 2 and 3 and also in columns 7 and 8, respectively, of Table 174 on page 465. The fifth difference osculatory formula requires the original data in five-year groups. Hence labor was saved by determining the mean population for the period 1901-1910 by five-year groups instead of by single ages. The group required is 4-8, 9-13, 14-18, etc., thus leaving the group 0-3 unused. For checking purposes the mean population for this group is also obtained. Hence in tape 266 the additions of the first four groups, 0-3, 4-8, 9-13, and 14-18, are shown, the population in 1910 on the right, that for 1900 in the center, and the ages at the beginning and end of each group on the left.

267. The totals obtained in tape 266 were then added in groups of five, the group 0-3 being set off by itself. After the addition of these totals a subtotal

was taken and the populations of unknown ages, shown at the bottom of columns 7 and 8 of Table 174 on page 465, were added, giving as totals the population at all ages at the beginning of columns 2 and 3 of this table, and also at the beginning of tape 264. This serves as a check on the work.

268. Since the computation of the life table from tape 174 to tape 187 requires population by single years of age, beginning with age 79 and extending to the end of life, these were copied from columns 7 and 8 of Table 174, page 465, and from tape 265 for ages 100 years and over and added in groups of five. The total should agree with those shown for the same age groups in tape 267, as indicated by the mark @. Of course, in actual practice this work would be shown at end of tape 266.

269. In order to distribute the population of unknown ages among those of known ages, the ratios of the total population to that of known ages, as shown in the totals and subtotals of tape 267, respectively, were obtained to ten significant figures and the 1900 ratio entered at the beginning of tape 269. This ratio, 1.001248232, was set up on the computing machine and each of the numbers on the left of tapes 267 and 268 multiplied by it, the products being entered in tape 269 just opposite the factors. The machine was split between banks 3-4, 6-7, and 14-15, the integral parts being entered in the center and the fractions on the right. On the left the initial age of each two out of five groups was entered. As in tape 265, where the fraction is .50 or over, it is preceded by 9 in bank 3 and the integral part increased by unity. The total of the fractions less than .50 diminished by the additions made in increasing the integral part by unity is .02 and the sum of the integers is 9,764,368, which agrees with the corresponding total in tape 267.

The populations by single years of age from 79 years to the end of life were then added in groups of five and their totals checked to those for the same age groups above, as indicated by the sign @. In the group 79-83 the total of the integers is 52,776 and that of the fractions .80, showing that another integer should be increased by unity. Accordingly, the population for age 81, whose fraction is .48, was increased by unity, 9 placed before the fraction, the total of the integers increased to 52,777, and 9 added in bank 3 in the total of the fractions; this result agrees with the one for this group shown above. These changes were made in ink.

270. Work for 1910, similar to that for 1900 in tape 269, is shown in tape 270. The ratio of total population to population of known ages, 1.000853884, is entered at the top and the numbers on the right of tapes 267 and 268 multiplied by it.

271. The integral parts of tape 269 were subtracted from corresponding integral parts of tape 270 and the remainders entered in corresponding positions in tape 271. Where the remainders were negative their complements were entered. At the end a subtotal was taken and 9,764,368, the total population from the

left side of tape 267, was added to it, so that the final total is 11,666,100, the population in 1910 from the right side of tape 267, and this served as a check on the work, as indicated by the mark  $\odot$ . The differences of population by single years of age were summed in five-year groups and their totals compared with the differences for the same age group just above, the equality being indicated by the sign  $\odot$ .

272. The factor  $\beta$  from tape 264 was then set up on the computing machine and multiplied by each of the differences in tape 271, the ages being entered on the left, the integral part of the product in the center, and the fractions on the right of tape 272. In the case of negative differences,  $\beta$  was multiplied by their complements, and then the complements of the products were entered upon the machine. Since the sum of the fractions which were dropped, diminished by the increases required to raise the integers by unity, is 8.94, it appears that one more increase was made than is required by the sum of the fractions. Hence, of the integers that were increased by unity the one having the smallest fraction was reduced. Accordingly, 74,018 was reduced to 74,017 and the 9 preceding its fraction was dropped, so that the total of the integers became 1,048,144 and that of the fractions 9.94, which indicates that the sum of the increases exceeds that of the fractions that were dropped by .06.

Then the sum of the differences in tape 271 was multiplied by  $\beta$  and the product entered just below the total taken on the machine. It will be noted that they agree exactly, and this serves as a check on the work.

The sum of the fractions in group 104-108 is 1.80, showing that two integers should have been increased by unity. Since all four differences in this group are equal, those for ages 104 and 105 were increased to zero. Hence, the fractions for these ages were preceded by 9's, the total of the integers increased to minus 2, or 9,999,998, and that for the fractions reduced to 9.80, which agrees with the product shown above for this group.

273.  $\alpha = 1.107343759$  was then set up on the computing machine and multiplied by  $P_{1900-June-1}$  from tape 264, the total number of females on June 1, 1900, and the product to the nearest integer entered upon the adding machine. This value was obtained according to equation (77) on page 354.

274. The integral parts of the products in tape 272 were then added to the corresponding populations in tape 269 and the sums set down in tape 274. These values were obtained according to equation (76) on page 354, and it will be noted that the total mean populations by these two processes are equal, as indicated by the mark  $\odot$ .

The populations by single ages 79 years and over were then added in groups of five and their totals compared with those for the same groups shown above, as indicated by the mark  $\odot$ .

# CALCULATION OF THE MEAN POPULATION OF WHITE FEMALES IN THE ORIGINAL REGISTRATION STATES FOR THE PERIOD 1901-1910

<sup>1</sup> The Wittstein and Spencer formulas were not used directly in computing the both sexes rates of mortality; instead the averages of the rates of mortality in the male and female life tables were used from ages 76 to 115 for the 1901 both sexes life table and from ages 90 to 115 for the 1910 both sexes life table.

PART VIII

ORIGINAL STATISTICS

---

---

## PART VIII.—ORIGINAL STATISTICS.

### THE SEVEN TYPES OF ORIGINAL STATISTICS.

275. All the original statistics used in the construction of the life tables are given in this part. The statistics for any given life table are all on one page. At the foot of each page will be found either the mortality statistics used to compute the number of births or else the number of registered births where they were used.

The original statistics of populations and deaths were not uniform, and they have been classified here under seven types, each of which is described below.

TYPE I includes all the statistics for the 1910 tables except those for the four cities. These are:

Populations estimated as of July 1, 1910, and reported deaths for the calendar years 1909-1911 by single years of age from birth to the end of life.

Deaths by months under 1 year of age for the calendar years 1909-1911.

Deaths by single years under age 5 for the calendar years 1912 and 1913, which were used in determining the number of births. For two of these tables the registered births for the period 1909-1911 are shown instead of the deaths used in determining the number of births.

See Tables 137 to 160, pages 428 to 451.

TYPE II includes all the statistics for the 1901 tables for the original registration states and its subdivisions except whites in cities and in the rural part. These are:

Populations estimated as of July 1, 1900, by single years of age from birth through age 99, ending with the group 100 years and over.

Reported deaths for the calendar years 1900-1902 by single years of age from birth to the end of life.

Deaths by months under 1 year of age for the calendar years 1900 and 1901.

Deaths by single years under age 5 for the calendar years 1903-1906, used in determining the number of births.

See Tables 161 to 170, pages 452 to 461.

TYPE III includes all the statistics for the 1901 tables for whites in cities and in the rural part of the original registration states. These are:

Populations estimated as of July 1, 1900, and reported deaths for the calendar years 1900-1902 by single years under age 5, then by quinquennial age groups through age 99, ending with the group 100 years and over.

Deaths by months under 1 year of age for the calendar years 1900 and 1901.

Deaths by single years under age 5 for the calendar years 1903-1906, used in determining the number of births.

See Tables 171 and 172, pages 462 and 463.

TYPE IV includes all the statistics of the four tables for the decennium 1901-1910 for whites and Negroes in the original registration states. These are:

Enumerated population June 1, 1900, by single years of age from birth through age 99, ending with the group 100 years and over.

Enumerated population April 15, 1910, by single years from birth to the end of life.

Mean population for the period 1901-1910 for the age group from birth through age 3, then by quinquennial age groups from age 4 through some old age, such as 78, and then by single years to the end of life. The age through which the quinquennial age groups were carried varied with the table. Reported deaths by single years of age for the period 1901-1910 from birth to the end of life.

Deaths by months under 1 year of age for the calendar years 1901 and 1905-1910.

Deaths by single years under age 5 for the calendar years 1901-1913, used in determining the number of births.

See Tables 173 to 176, pages 464 to 467.

TYPE V includes all the statistics for the two tables for Negroes in the District of Columbia for the decennium 1901-1910. These are:

Enumerated population June 1, 1900, by single years of age from birth through age 99, ending with the group 100 years and over.

Enumerated population April 15, 1910, by single years from birth to the end of life.

Mean population for the period 1901-1910 for the age group from birth through age 3, then by quinquennial age groups through age 63 in one table and through age 78 in the other, and then by single years to the end of life.

Reported deaths for the period 1901-1910 by single years under age 5, then by quinquennial age groups through age 94, ending with the group 95 years and over.

Deaths for the period 1905-1910 by single years from birth to the end of life.

Deaths by months under 1 year of age for the period 1905-1910.

Deaths by single years under age 5 for each of the calendar years 1901-1913, used in determining the number of births.

See Tables 177 and 178, pages 468 and 469.

TYPE VI includes all the statistics for the 1901 tables for the states and the 1890 tables for Massachusetts. For the 1901 tables, these are:

Populations estimated as of July 1, 1900, by single years under age 5, then by quinquennial age groups through age 99, ending with the group 100 years and over.

Reported deaths for each of the calendar years 1900-1902 by single years under age 5, then by quinquennial age groups through age 94, ending with the group 95 years and over.

Deaths by single years under age 5 for each of the calendar years 1903-1906, used in determining the number of births. For two of the tables in this sixth type the number of births registered in the calendar years 1900-1902 are given instead of the deaths used to determine the number of births.

For the two Massachusetts tables for the census year ending May 31, 1890, the following statistics are given:

Enumerated population June 1, 1890, and also for June 1, 1900, by single years under age 5, then by quinquennial age groups through age 99, ending with the group 100 years and over.

Population estimated as of December 1, 1899, for the same ages and age groups as the enumerated populations.

Reported deaths for the census year ending May 31, 1890, by single years under age 5, then by quinquennial age groups through age 94, ending with the age group 95 and over.

See Tables 179 to 181, pages 470 to 472.

TYPE VII includes all the statistics for the four life tables of any one city, and the four cities for which life tables are shown are Boston, Chicago, New York, and Philadelphia.

On the left side of each table are:

Population, estimated as of July 1, 1910, and reported deaths for the calendar years 1909-1911 by single years under age 5, then by quinquennial age groups through age 99, ending with the group 100 years and over.

On the right side of each table are:

Population, estimated as of July 1, 1900, and reported deaths for the calendar years 1900-1902 by single years under age 5, then by quinquennial age groups through age 94, ending with the group 95 years and over.

At the bottom of each table are:

Reported deaths by single years under age 5 for the calendar years 1903-1906 and 1912 and 1913, used in determining the number of births. The number of births registered are given for six of the tables in the calendar years 1909-1911 and for two tables in the calendar years 1900-1902.

See Tables 182 to 185, pages 473 to 476.

**ASSUMPTIONS MADE TO FILL IN STATISTICS WHICH WERE LACKING.**

276. Statistics for the tables of both sexes are simply the sum of those for males and females given in Tables 137, 138, 161, and 162, pages 428, 429, 452, and 453.

Where the populations estimated as of July 1, 1910, were given by single years of age from birth to the end of life, while those estimated as of July 1, 1900, ended with the age group 100 years and over, the latter was distributed into populations by single years of age by assuming that these were proportional to those of July 1, 1910. This distribution into single years of age, 100 years and over, is shown for white females in the original registration states in section 265 and the corresponding tape on pages 413 and 411, respectively.

Where the deaths by months under 1 year of age were shown only for the two calendar years 1900 and 1901, it was assumed that they were proportional to those in the period 1900-1902. In the same way where the deaths by months under 1 year of age were available only for 1901 and for 1905-1910, or where they were available for only the period 1905-1910, it was assumed that these deaths for any month of age were proportional to the deaths for that month of age during the decennium 1901-1910.

Where the reported deaths for the period 1901-1910 were given only by single years under age 5, then by quinquennial age groups through age 94, ending with the group 95 years and over, while the reported deaths for the period 1905-1910 were given by single years from birth to the end of life, it was assumed that the deaths in any year of age during the decennium 1901-1910 were proportional to those during the period 1905-1910.

Only the total number of births, 17,957, was reported in Boston in 1911. It was assumed that the numbers of births by sex in this year were proportional to the sums of those by sex in the calendar years 1909 and 1910, which were 18,088 males and 17,257 females.

To compute the number of births needed for the calculation of the two 1890 Massachusetts life tables by the method used for the other life tables, it was assumed that the population enumerated June 1, 1890, and the reported deaths during the census year ending May 31, 1890, by single years under age 5, remained constant for five years.

**DISTRIBUTION OF POPULATION AND MORTALITY STATISTICS OF UNKNOWN AGES AND UNKNOWN NATIVITY.**

277. The distribution of populations of unknown ages in the census returns of June 1, 1900, and April 15, 1910, were made for all the 1901 and 1910 life tables under the direction of the Geographer. The distribution of populations of unknown ages in the census returns of June 1, 1890, as well as those of the census of June 1, 1900, and April 15, 1910, which were used in the computation of the life tables for the decennium 1901-1910, were made in the Division of Vital Statistics. The distribution of deaths of unknown ages for all tables was made in the Division of Vital Statistics. The general method shown in sections 269 and 270 and the tapes which correspond to them, pages 412 and 413, was followed in distributing populations and deaths of unknown ages.

The distribution of deaths among whites of unknown nativity between native whites and foreign-born whites in the original registration states was made in the Division of Vital Statistics. It was assumed that in any quinquennial age group the number of deaths of native whites and of foreign-born whites, respectively, among whites of unknown nativity were proportional to the number of deaths of known nativity among native whites and among foreign-born whites, respectively.

**ESTIMATES OF POPULATIONS.**

278. All estimates of populations as of July 1, 1900, and July 1, 1910, were made under the direction of the Geographer, while the estimates of populations as of July 1, 1901, and as of December 1, 1899, and the computation of the mean populations for the decennium 1901-1910 were made in the Division of Vital Statistics. With the exception of the mean population for the decennium 1901-1910 the general method used in estimating populations of a given date is that shown in section 256 and the accompanying tape, pages 408 and 409. The method used to obtain the mean population for the decennium 1901-1910 is given in sections 264 to 274 and the accompanying tapes, pages 410 to 414.

## NUMBER OF BIRTHS REGISTERED AND COMPUTED NUMBER OF BIRTHS.

279. The number of births registered is shown by sex in each of the calendar years 1900–1902 and 1909–1911 for Indiana, Massachusetts, Michigan, Boston, and New York City, except that the number of registered births in Boston in 1911 was not separated by sex and in Indiana the number of registered births is from October 1, 1899, to September 30, 1900.

instead of for the calendar year 1900; also the number of registered births is shown by sex for the period 1909–1911 in the state of New York and in Philadelphia, and for the census year ended May 31, 1890, in the state of Massachusetts. Registered births without distribution by sex are shown for the periods 1900–1902 and 1909–1911 in New Jersey; also for the period 1900–1902 in the state of New York and in Philadelphia.

TABLE 136.—COMPUTED NUMBER OF BIRTHS AND NUMBER OF BIRTHS REGISTERED.

| LIFE TABLE.                                           | NUMBER OF BIRTHS. <sup>1</sup> |             |             |           |             |             |
|-------------------------------------------------------|--------------------------------|-------------|-------------|-----------|-------------|-------------|
|                                                       | MALE.                          |             |             | FEMALE.   |             |             |
|                                                       | Computed.                      | Registered. | Difference. | Computed. | Registered. | Difference. |
| <b>ORIGINAL REGISTRATION STATES:</b>                  |                                |             |             |           |             |             |
| Total—                                                |                                |             |             |           |             |             |
| 1901.....                                             | 814,484                        |             |             | 777,099   |             |             |
| 1910.....                                             | 922,172                        |             |             | 877,281   |             |             |
| White—                                                |                                |             |             |           |             |             |
| 1901.....                                             | 798,235                        |             |             | 761,085   |             |             |
| 1901–1910.....                                        | 2,836,683                      |             |             | 2,699,663 |             |             |
| 1910.....                                             | 905,222                        |             |             | 860,378   |             |             |
| Negro—                                                |                                |             |             |           |             |             |
| 1901.....                                             | 15,537                         |             |             | 15,338    |             |             |
| 1901–1910.....                                        | 53,421                         |             |             | 52,861    |             |             |
| 1910.....                                             | 16,154                         |             |             | 16,103    |             |             |
| Native white—                                         |                                |             |             |           |             |             |
| 1901.....                                             | 780,850                        |             |             | 744,085   |             |             |
| 1910.....                                             | 880,614                        |             |             | 836,211   |             |             |
| Whites in cities—                                     |                                |             |             |           |             |             |
| 1901.....                                             | 470,444                        |             |             | 449,606   |             |             |
| 1910.....                                             | 585,325                        |             |             | 559,071   |             |             |
| Whites in rural part—                                 |                                |             |             |           |             |             |

<sup>1</sup> In the computation of the 1901 and 1910 life tables the number of births during the periods 1900–1902 and 1909–1911, respectively, was used.

<sup>2</sup> The number of births registered was given only by white and colored, while the number of Negro births was computed.

<sup>3</sup> Census year ended May 31, 1890.

<sup>4</sup> Compiled from number of births registered by calendar months in Registration Reports of Massachusetts, 1889 and 1890.

<sup>5</sup> The number of births registered was used in determining the rates of mortality for the life table.

<sup>6</sup> The number of births registered by sex was not available; the figures given under males include both sexes.

The number of births of colored people registered by sex in the District of Columbia is shown for each of the calendar years 1901-1910.

The number of births was computed for each of the 74 life tables and was used in the computation of the rates of mortality except for the 1901 and the 1910 tables for Massachusetts and Boston and the 1910 tables for the cities of New York and Philadelphia, where the number of registered births was used in the computation of the rates of mortality. Table 136 shows the computed number of births, the number of births registered, and the difference between them where the number of births registered is available.

The theory employed in the computation of births is given in sections 106 to 110 on pages 338 to 342, and the actual computation of the number of male births in the state of New York, 1909 to 1911, is given in sections 140 to 142 and in the diagrams and tape which correspond to them on pages 371 and 373, respectively.

#### MEANING OF URBAN AND RURAL AS USED IN THE LIFE TABLES.

280. On page 18 of the 1909 Mortality Statistics the following definition is given:

By urban population is understood, for the mortality statistics, the population of cities or municipalities (including New England "towns") that had 8,000 or more inhabitants in 1900, while the population of the remainder of a state is considered as rural.

In Volume I of the Report of the Thirteenth Census of the United States, relating to Population, 1910, the following definition appears on page 53:

The Census Bureau classifies as urban population that residing in cities and other incorporated places of 2,500 inhabitants or more, including New England towns of that size.

In order to obtain populations to agree with the deaths for the 1901 life tables for whites in cities, it was necessary to add together the white populations of the original registration states in all cities or municipalities that had 8,000 or more inhabitants in 1900. In this way populations were obtained as of June 1, 1900, and also as of April 15, 1910.

To obtain the populations for the 1901 life tables for whites in rural part of the original registration states, it was necessary to subtract from the total white population of the original registration states the white populations of the cities mentioned above.

A note at the beginning of Table 1 on page 67 in the 1910 Mortality Statistics reads as follows:

The term "cities" as used in this table is restricted to municipalities having 10,000 or more inhabitants in 1910, smaller places being included with the "rural part of the registration states."

This defines "cities in the original registration states" and "rural part of the original registration states" in 1910, as far as deaths are concerned.

By comparing Table 1 in the 1909 Mortality Statistics with Table 1 in the 1910 Mortality Statistics on pages 67 to 80, it will be noted that because of this change in the definition of "cities" 17 municipalities were transferred from urban to rural area and 20 other municipalities were transferred from rural to urban area. The deaths for whites in cities in the original registration states in 1909 included those of the 17 municipalities which were transferred from urban to rural area in 1910, but did not include those of the 20 other municipalities which were transferred from rural to urban area in 1910. This did not affect materially the number of deaths among whites in cities and among whites in rural part of the original registration states for 1910.

In the 1910 Population Report, Volumes II and III, reports by states are given, and at the end of each report are "notes regarding the changes in boundaries, etc., of incorporated places." By looking up these notes for each of the original registration states, it will be seen that during the period 1900-1910 there were a number of annexations from the rural area to the individual cities of the original registration states. Populations for some of the important ones are given in Bulletin 122 on page 4.

On this account the rural and urban tables of 1901 and 1910 do not include exactly the same area. However, the change was so slight that it does not affect materially comparisons of the tables at the two epochs.

In order to obtain populations to agree with the death statistics of whites in cities for the 1910 life table, it was necessary to add together the white populations of those municipalities having 10,000 or more inhabitants in 1910 for the census returns of both June 1, 1900, and April 15, 1910, taking into account the annexations and other changes in the ten-year period. Then, to obtain the rural white populations of the original registration states in 1910, the total white population in the cities mentioned above were subtracted from the white population of the original registration states for the census returns of both June 1, 1900, and April 15, 1910.

<sup>1</sup> Deaths by months under 1 year of age in 1902 are not available. Hence deaths by months in columns 6 and 11 include only those in 1900 and 1901.

TABLE 173 POPULATION AND MORTALITY STATISTICS UPON WHICH IS BASED THE  
LIFE TABLE FOR WHITE MALES IN THE ORIGINAL REGISTRATION STATES: 1901 TO 1910.

Unknown ages undistributed in enumerated population, but distributed in mean population and in deaths.

TABLE 174 POPULATION AND MORTALITY STATISTICS UPON WHICH IS BASED THE  
LIFE TABLE FOR WHITE FEMALES IN THE ORIGINAL REGISTRATION STATES: 1901 TO 1910.

Unknown ages undistributed in enumerated population, but distributed in mean population and in deaths.

| AGE<br>INTERVAL. | POPULATION.                 |                               |                     | REPORTED<br>DEATHS,<br>1901-1910. | AGE<br>INTERVAL. | POPULATION.                 |                               |                     | REPORTED<br>DEATHS,<br>1901-1910. |

# INDEX.

- $a$ , constant in Wittstein's formula, section 117, p. 348.  
 log log  $a$ , equation (49), p. 349; equation (84), p. 394.  
 log log  $a$ , mean value of, section 119, p. 349; tapes 199, 200, p. 397.
- $a_x$ , life annuity due. *See* Life annuities.  
 values of, for white males, p. 298.  
 for white females, p. 312.
- $A_x$ , net single premiums. *See* Premiums.  
 values of, for white males, p. 300.  
 for white females, p. 314.
- Abridged life tables, construction of, footnote, p. 372.
- Absolute totals, section 128, p. 354; pp. 355, 356; pp. 358 to 360.
- Accumulated deviation of expected from actual deaths, p. 360.
- Actual deaths, deviation of expected deaths from, pp. 356, 360.
- Actual population, average death rates in, section 64, p. 42.  
 comparison of, with those in stationary population, section 65, p. 43.
- Actuarial Society of America, p. 13; section 90, p. 224.
- Actuaries, life tables of service to, p. 13.  
 construction of life table for males in the state of New York of interest to, section 13, p. 21.  
 mathematical theory for information of, section 12, p. 20.  
 parts of text designed for, section 1, p. 17.
- Adjusted deaths, section 136, p. 370; graph 136, p. 371.  
 used in drawing graphs, table 129, p. 364.
- AF, symbol for Four French Offices Mortality Experience, 1819-1887, section 90, p. 224.
- Age, advanced, Wittstein's formula modified for, section 117, p. 348.  
 last, in life table, equation (56), p. 352.  
 old, rates of mortality employed to determine constants in Wittstein's formula, section 119, p. 349.  
 unknown, distribution of statistics of, section 277, p. 424.
- Age—  
 axis, section 96, p. 329.  
 distribution of stationary population, section 55, p. 40.  
 group. *See* Quinquennial age groups.  
 interval, defined, section 17, p. 25; column 1 of tables in Parts II and VIII.  
 current, section 17, p. 25.  
 of decedents varies with birth and registration intervals, sections 101 to 103, pp. 333, 334.  
 of a population equals its birth interval, section 100, p. 333.  
 older, section 17, p. 25.  
 population in current, section 22, p. 27; column 6 of tables in Part II. *See* Stationary population.  
 subdivisions of, under 1 month, table 129, p. 364.  
 subdivisions of, under 1 year. *See* Months of age under 1 year.  
*See* Interval.  
 limit of human life, section 84, p. 48; section 95, p. 329; section 117, p. 348.
- Aggregate of the dead who—  
 died in same time interval and same age interval, diagram 10 and equation (12), p. 335.  
 were born in same time interval, and who died in same age interval, diagram 8, p. 333; equation (9), p. 334.  
 and who died in same time interval, diagram 9 and equation (11), p. 334.
- Aggregate of those—  
 living at same time, or population, section 100 and equation (8), p. 333.  
 birth and age intervals covered by, diagram 7, p. 333.  
 surviving to same age, section 99 and equation (6), p. 332.  
 birth and time intervals covered by, diagram 6, p. 332.
- Aggregate tables, section 92, p. 225.
- Aggregates:  
 relation between, of the living and of the dead, section 104, p. 335; diagram 12 and equations (14) and (18), p. 336.  
 statistical,  $P_z^{x_1/x_2}$ , section 100, p. 333.  
 $D_z^{x_1/x_2}$ , section 103, p. 334.  
 expression of rate of mortality in terms of, section 105, p. 336; equation (24), p. 338.
- Aggregates of the dead. *See* Aggregate of the dead who—  
 type one, section 101, p. 333.  
 type two, section 102, p. 334.  
 type three, section 103, p. 334.  
 in terms of aggregates of the living and force of mortality, equations (20), (21), p. 337.  
 integration to determine number in, diagram 11, p. 335.

Bureau of the Census, p. 13.

computations of life table functions made in, for—

foreign countries, footnote, p. 203.

life insurance mortality tables, footnote, p. 225.

mortality statistics by months in Bulletin 109 of, footnotes, p. 340.

original statistics—

for life tables furnished by, section 15, p. 21; section 95, p. 329.

of annexations given in Bulletin 122 of, section 280, p. 426.

second official publication on life tables by, section 1, p. 17.

urban and rural defined by, section 280, p. 426.

$c_x$ , equation (31), p. 344.

$C$  designates that computed number of births were used in construction of life table, column 3, pp. 416, 418.

$C_x$ , commutation column, pp. 302 to 311; pp. 316 to 325.

Cabinet Impérial, Bureau de la Statistique Générale, Table de Mortalité des Japonais, footnote, p. 203.

Calculations to illustrate—

computation of number of births, section 106, p. 338; section 109, p. 340. See Births.

factors used in, table 109, p. 340. See also Percentage.

## Calculations to illustrate—Continued.

## process of computing—

- annual rates of mortality by single years under 5, section 111, p. 342; table 111, p. 343.
- monthly rates of mortality under 1 year, section 112 and table 112, p. 343.

## special process used—

- to determine mean population, 1901-1910, tapes 264 to 274, pp. 411, 412, 414. See Whites in original registration states, mean populations for.

- to join infant mortality curve with that by osculatory interpolation, tapes 250 to 263, p. 409.

- standard process of construction of the life table, graph 136, p. 371; pp. 373, 377, 381, 384, 385, 387, 389, 391, 393, 397, 399, 403, 405, 407; sections 237 to 239, p. 406; sections 244 to 249, pp. 406 and 408.

- descriptive text and photographed tapes used in, section 133, p. 369.

- involves more than one hundred steps, section 13, p. 21.

- life table for males in the state of New York, 1910, selected as typical table for, section 125, page 352.

- operations in, not represented by tapes, diagrams, or graphs, footnote, p. 10.

- questions and answers concerning, section 85, p. 48.

## Canada, section 90, p. 224.

## Carlisle Life Table, section 11, p. 20; section 93, p. 297.

## Census. See also Bureau of the Census.

- difference between mortality tables derived from experience of insurance companies and that from, statistics, section 76, p. 46; section 92, p. 225.

## United States, section 100, p. 333.

- Report of the Thirteenth, of the, section 280, p. 426.

## Central—

- death rate. See Death rate.

## term of a series of—

- 15 terms, graduated, section 118, p. 349; equation (45), p. 349.

- 21 terms, graduated, equation (50), p. 350.

## Checks on calculation:

- equations for, (83), p. 390; (86), p. 400; (87) and (88), p. 404.
- symbols used to indicate, section 138, p. 371.

## Chicago, section 2, p. 17.

- average death rate of total population at birth in, section 63, p. 42.

- births in, computed number of, p. 425.

- deaths in, by days and weeks under 1 month of age used in drawing infant mortality graphs for cities, section 132, pp. 364, 365.

- life tables for, pp. 176 to 183.

- tabular outline for construction of, p. 418.

- original statistics for life tables for, p. 474.

- belong to type VII, section 275, p. 424.

## Circle inclosing number, section 138, p. 371. See Checks on calculations.

## Cities of the original registration states, whites in, section 2, p. 17.

- additional mortality statistics used in drawing graphs of life table functions for, section 132, pp. 364, 365.

- age at which generation is reduced by one-half among, section 42, p. 35.

- births among, computed number of, p. 425.

## complete expectation of life among:

- change in, between 1901 and 1910, section 52, p. 39.

- compared with that in rural districts and in foreign countries, section 53, p. 39.

- graphs of, compared with that in rural districts in 1910, p. 279.

- graphs of, 1901 and 1910, p. 276.

- deaths among, out of 100,000 born alive, graphs of number of: compared with that in rural districts in 1910, p. 269.

- in 1901 and in 1910 compared, p. 266.

- determination of population to agree with reported deaths among, section 280, p. 426.

- life tables for, pp. 104 to 111.

- compared with those in rural part by means of graphs, section 8, p. 19.

- tabular outline for construction of, p. 416.

- meaning of, as used in the life tables, section 280, p. 426; note, pp. 104 to 111.

## measure of vitality among:

- graphs of, compared with that in rural districts in 1910, p. 289.

- graphs of, 1901 and 1910, p. 286.

- monthly, section 62, p. 42.

## Cities of the original registration states, whites in—Continued.

## original statistics for:

- 1910, pp. 438, 439.

- 1901, p. 462.

- belong to type I and type III, respectively, section 275, p. 423.

## rates of mortality among:

- calculation of, for females, 1901, used to illustrate process of joining infant mortality curves with osculatory fifth difference curves, section 134, p. 369; tapes 250 to 263, p. 409.

- change in, for males, section 32, p. 31.

- change in, for females, section 34, p. 32.

- compared with that in rural districts, section 35, p. 33.

- graphs of, compared with that in rural districts in 1910, p. 249.

- graphs of, 1901 and 1910, p. 246.

## survivors among, number of:

- diagram of, showing deviation from the mean, section 45, p. 36.

- graphs of, compared with that in rural districts in 1910, p. 259.

- graphs of, 1901 and 1910, p. 256.

- Closed area, number of deaths in, diagram 5, p. 332.

- Colored races. See India, Japan, Negroes.

- Columns of life tables, fundamental, explained, sections 17 and 18, p. 25.

- derived, explained, sections 19 to 26, pp. 26 to 29.

- Common ordinate, radius of curvature, and tangent, section 113, p. 344; section 116, p. 348. See Assumptions for osculatory interpolation curves.

- Commutation columns, section 11, p. 20.

- based on life tables for whites in the original registration states, 1910, section 11, p. 20; section 94, p. 297.

- for calculation of values on single lives, section 94, p. 297.

- questions and answers concerning, section 83, p. 47.

## values of:

- for males, pp. 302 to 311.

- for females, pp. 316 to 325.

- Comparative Accuracy of Different Forms of Quinquennial Age Groups*, The, footnote, p. 362.

- Complement of subtrahend used in subtraction, section 138, p. 370.

- Complete expectation of life, p. 13.

- age at which maximum, occurs, section 50, p. 38.

- among insured lives, p. 232.

- questions and answers concerning, section 81, p. 47.

- at any age compared with population in current and all older age intervals, section 56, p. 40.

- at birth, section 49, p. 37.

- at older ages, section 53, p. 39; section 124, p. 352.

- by months under 1 year of age, diagram D, pp. 274 to 277, 279.

- See INFANT MORTALITY of tables in Part II.

- description of diagram D in the graphs of, section 51, p. 38.

- calculation of, from age 80 to end of life, section 124, p. 352.

- change in, between 1901 and 1910, section 52, p. 38.

- comparison of, in different classes, section 53, p. 39.

## computed for—

- males in the state of New York, 1910, sections 243, 246, p. 406.

- some of the foreign and insurance life tables, footnotes, pp. 203, 225.

- equation for, (57), p. 352.

- explanation of, section 21, p. 26.

- graphs of, pp. 274 to 283.

- greater for females than for males, section 53, p. 39.

- in foreign countries, pp. 216 to 219.

- questions and answers concerning, section 73, p. 45.

- maximum, section 50, p. 38.

- questions and answers concerning, sections 49 to 53, pp. 37 to 39.

- symbol for,  $2x$ . See heading of column 5 in tables of Part II.

- variation in, section 51, p. 38.

- with average death rate, section 67, p. 43.

## Computing machine, section 123, p. 351.

## Connecticut, section 2, p. 17.

## Connection between flow of a population and time and age, diagram 1, p. 329.

## Constants in—

- fifth difference osculatory interpolation formula, section 113, p. 345.

- modified Lagrange formula for central death rate:

- general equation for, (64), p. 352.

- specific equation for, (89), p. 408.

## Constants in—Continued.

- Spencer's 21-term formula, equation (50), p. 350.  
 Waters's formula for mean population, equations (70), (71), p. 353; (76), (77), p. 354.  
 Wittstein's formula:  
   general equation for, (43), p. 348.  
   specific equations for, (48), (49), p. 349; (84), (85), pp. 394, 396.

## Construction—

- of a life table:  
   abridged, footnote, p. 372.  
   detailed, section 13, p. 21; Part VII.  
   divided into three main sections, section 95, p. 329.  
   mathematical theory of, p. 13; section 12, p. 20; Part VI.  
   questions and answers concerning, section 84, p. 48.  
   special processes used in, section 14, p. 21; sections 125 to 127, pp. 352, 353; tapes 250 to 274, pp. 409, 412, 414.  
   two important theorems used in, section 98, p. 331.  
   variations from standard, section 14, p. 21.  
 of each life table, extra information needed for, section 14, p. 21; section 135, p. 369; pp. 416 to 419.

Continuous addition, interpolation by, sections 154 to 168, pp. 376 to 386.

Correction, determination of fifth difference, section 115, p. 346.

Countries. *See* Foreign countries. *See also* Detailed Table of Contents, p. 5.

Crelle's Rechenregeln, sections 207, 208, p. 398.

## Current—

- age interval, defined, section 17, p. 25.  
 time, section 96, p. 329.

Czuber, footnote, p. 329.

$d_x$ , defined, section 19, p. 26. *See* Deaths out of 100,000 born alive, symbol for.

$d_x^{(m)}$ , section 124, p. 351. *See* Deaths out of 100,000 born alive, by months, symbol for.

$D_x$ , commutation column, pp. 302 to 311, 316 to 325.

$D_{x_1/x_2}^{1/2}$ , definition of, section 101, p. 333; equations (9), (10), p. 334.

$D_{x_1/x_2}^{1/2}$ , definition of, section 102, and equation (11), p. 334.

$D_{x_1/x_2}^{2/2}$ , definition of, section 103, p. 334; equation (12), p. 335.

$D_{x_1/x_2}^{z/z+1}$ , special case of, equation (13), p. 335.

$D_a$ ,  $D_b$ ,  $D_c$ ,  $D_d$ , diagram 12, p. 336.

$D_{\delta}^{(12)}$ , section 124, p. 351.

Denmark, Statistisk Tabelvaerk, footnote, p. 203.

Davis, Dr. William H., p. 13.

Dead, aggregate of the. *See* Aggregate of the dead.

## Death rate:

- average annual, per thousand:  
   calculation of, for males in the state of New York, 1910, section 247, p. 406.  
   change in, with age, section 68, p. 43.  
   comparison of, in actual with that in stationary population, section 65, p. 43.  
   determination of, for sections of stationary population, section 26, p. 29; section 66, p. 43.  
   equation for, (59), p. 352.  
   explanation of, section 25, p. 28.  
   greater change in, at birth in cities than in states, section 63, p. 42.  
   in actual population, section 64, p. 42.  
   in various cities, states, and areas. *See* under name of same.  
   of total population at birth, section 63, p. 42.  
   variation of, with expectation of life, section 67, p. 43.  
 central, definition of, equation (24), p. 338.  
   equation for, based on Lagrange's theorem, equation (60), p. 352.  
   expected deaths obtained by use of, section 263, p. 410.  
   rate of mortality in terms of, equation (24), p. 338; equation (91), p. 410.  
   symbol for,  $m_x$ , equation (24), p. 338.  
   transformation of equation for, to shorten work, equations (61), (62), p. 352.

Death statistics, section 275, p. 423. *See* Original statistics.

Deaths, annual, belong to two generations, section 54, p. 39.  
   between ages  $x=g(t)$  and  $x=h(t)$  of those born in the interval  $(t_1, t_2)$ , equation (5), p. 332.

## Deaths—Continued.

- by days, table 129, p. 364; equation (27), p. 340.  
   months, equation (25), p. 340. *See* Months.  
   single years of age under 5, used in determining number of births, types I to VII, section 275, p. 423.  
   weeks, table 129, p. 364; equation (26), p. 340.  
 deviation of expected, from actual, a test for conformity to original statistics, section 128, p. 355.  
   among whites in the original registration states, 1910, p. 356.  
   variation of, according to quinquennial age group, p. 360.  
 distribution of, of unknown age and unknown nativity, section 277, p. 424.  
 equation for graduated number of, at central age of a series of fifteen ages, equation (47), p. 349.  
   modified to simplify calculations, equation (82), p. 390.  
 expected, method of computing number of, section 128, p. 356.  
   equal to actual, condition for modified Lagrange formula, equation (63), p. 352.  
 number of, in closed area, diagram 5, p. 332.  
   total, upon which life tables were based. *See* headings of tables in Part II.

## Deaths—

- out of 79,116 alive at age 20 among insured lives, number of, p. 230.  
   graphs of, p. 273.  
 out of number alive by original radix of each table, number of, p. 238.

## Deaths out of 100,000 born alive, number of:

- by months under 1 year, diagram D, pp. 264 to 269. *See* Infant mortality tables.  
   symbol for,  $d_x^{(m)}$ , equations (54), (55), (58), pp. 351, 352.  
 derivation of, from number of survivors in table 56, sections 238, 240, p. 406.  
 explanation of, section 19, p. 26.  
 graphs of, pp. 264 to 272.  
 incidence of, section 47, p. 37.  
 in foreign countries, section 72, p. 44; pp. 212 to 215.  
 maximum, after infancy, section 72, p. 45.  
 symbol for, between ages  $x$  and  $x+1$  years,  $d_x$ , section 19, p. 26. *See* column 3 of tables in Part II.  
 variation of, with number of survivors and rate of mortality, section 48, p. 37.

## Deaths among males in the state of New York, reported number of, 1909-1911, p. 450.

- adjustment of, by months under 1 year of age, section 136, p. 370; graph 136, p. 371.  
 arranged graphically as first step in determining number of births, diagram 15, p. 338; diagram 140, p. 373.  
 distribution of, according to year of birth, diagram 17, p. 341; diagram 141, p. 373.  
 factors in table 109 applied to, in diagram 15, diagram 17, p. 341.  
 graduation of, by formula for graduated central term of a series of fifteen values of a function, tapes 174 to 180, pp. 389, 391.  
 graduation and interpolation of, by osculatory fifth difference formula, tapes 147 to 153, pp. 373, 377; tapes 162 to 168, pp. 385, 387.  
 graphic representation of, diagram 15, p. 338.  
 used in determining the number of births, table 106, p. 338; p. 450.

Decedents, percentage of, born in earlier and later calendar year. *See* Percentage of decedents born in.

Decimal point indicated by vertical lines, section 138, p. 370.

## Definition of—

- $d_x$ ,  $l_x$ ,  $L_x$ , in terms of aggregates of the living and of the dead, section 123, p. 351.  
 life table functions, sections 17 to 25, pp. 25 to 29.  
 urban and rural, section 280, p. 426.  
*See* Equations, defining.

## Degree, osculatory interpolation curve of the fifth, equation (38), p. 345.

- derivation of formula for, section 113, p. 344.  
 notation of, adapted to succession of  $y_x$  curves, equation (39), p. 345.

$u_x$  and  $v_x$  of the fourth, equations (32), (33), p. 344.

$\psi_x$  of the fifth, equation (35), p. 344.

modified Lagrange formula of the third, equation (62), p. 352.

$\delta$ , finite differences of fractional intervals, sections 114, 115, pp. 345, 346.

finite differences of unit intervals, section 116, p. 347; tapes 154, 155, 158 to 161, 163, 165 to 168, 228, pp. 377, 381, 384, 385, 387, 405.

- $\delta_{x/x+\epsilon}$ , equation (17), p. 336.  
 $\delta_{x/x+\epsilon}$ , section 105, p. 337.  
 $\delta_{x/x+\epsilon}^{(12)}$ , table 112, p. 343.  
 $\Delta$ , finite unit difference, section 97, p. 331; sections 113 to 115, pp. 344 to 346.  
 finite differences of quinquennial intervals, sections 116, 118, pp. 347, 349.  
 difference between population at same age at different periods, section 127, equation (72), p. 353; tape 271, p. 412.  
 Denmark:  
 annual rate of mortality in, pp. 204 to 207.  
 compared, section 70, p. 44.  
 complete expectation of life in, pp. 216 to 219.  
 compared, section 73, p. 45.  
 deaths in, out of 100,000 born alive, number of, pp. 212 to 215.  
 compared, section 72, p. 45.  
 measure of vitality in, pp. 220 to 223.  
 compared, section 74, p. 45.  
 computed in the Bureau of the Census, footnote, p. 203.  
 mortality functions shown for, section 69, p. 44; section 88, p. 203.  
 epoch of, section 87, p. 203.  
 Statistisk Tabelvaerk, footnote, p. 203.  
 survivors in, out of 100,000 born alive, number of, pp. 208 to 211.  
 compared, section 71, p. 44.  
 Derivation of—  
 coefficients for corrected unit fifth differences in osculatory interpolation formula, table 114, p. 347.  
 leading fractional differences in terms of leading integral differences, table 113, p. 346.  
 operand in Spencer's 21-term formula, table 134, p. 398.  
 osculatory fifth difference formula, section 113, p. 344.  
 Derivation of the *United States Mortality Tables by Osculatory Interpolation*, footnote, p. 344.  
 Derived mortality functions. *See* Mortality functions.  
 Descriptive text and photographs of tapes, section 133, p. 369.  
 Deutschen Reichs, Statistik des, section 107, p. 339; footnote, pp. 203, 339.  
 Deviation—  
 from mean—  
 in graphs of complete expectation of life, diagram C, pp. 274, 276, 277, and 279.  
 in graphs of measure of vitality, pp. 284 to 289.  
 in graphs of survivors, section 45, p. 36; diagram C, pp. 254 to 259.  
 of expected from actual deaths. *See* Deaths, deviation of.  
 accumulated, p. 360.  
 of rates of mortality for each quinquennial age group from those for the average group in table 122, table 123, p. 358.  
 weighted squared, of graduated from observed rates of mortality in table 122, table 126, p. 361.  
 Diagonal lines, used to indicate current time, the  $z$  lines, section 96, p. 329.  
 Diagram of—  
 annual rates of mortality by months under 1 year, diagram D, pp. 244 to 249.  
 method of computing values for, section 132, p. 364.  
 questions and answers concerning, section 30, p. 30.  
 complete expectation of life by months under 1 year, diagram D, pp. 274 to 277, 279.  
 described, section 51, p. 38.  
 deaths out of 100,000 born alive, by months under 1 year, number of, diagram D, pp. 264 to 269.  
 measure of vitality by months under 1 year, diagram D, pp. 284 to 289.  
 questions and answers concerning, section 62, p. 42.  
 monthly rates of mortality under 1 year, diagram D, pp. 244 to 249.  
 survivors out of 100,000 born alive, by months under 1 year, number of, diagram D, pp. 254 to 259.  
 questions and answers concerning, section 44, p. 36.  
 Diagrams—  
 A, B, C, and D in graphs of rates of mortality, pp. 244 to 253.  
 description of scales for, section 29, p. 30.

 variations in form of curve of, section 46, p. 37.  
 English Life Tables, section 93, p. 297.  
 No. 8, section 41, p. 34; section 131, p. 364.  
 Equations, defining—  
 $D_{x_1/x_2}^{1/4} = E_{x_1}^{1/4} - E_{x_2}^{1/4}$ , type one aggregate of the dead, equation (10), p. 334.  
 $D_{x_1/x_2}^{1/4} = P_{x_1}^{1/4} - P_{x_2}^{1/4}$ , type two aggregate of the dead, equation (11), p. 334.  
 $D_{x_1/x_2}^{1/4} = E_{x_1}^{1/4} - P_{x_2}^{1/4} - E_{x_2}^{1/4} + P_{x_1}^{1/4}$ , type three aggregate of the dead, equation (12), p. 335.  
 $\delta_{x/x+\epsilon} = P_{x_1}^{1/4} - P_{x_2}^{1/4}$ , equation (17), p. 336.  
 $\frac{\partial F(t, x)}{\partial t} = f(t, x)$ , rate at which persons born at time  $t$  survive to age  $x$ , equation (2), p. 331.

## Equations, defining—Continued.

$-\frac{\partial f(t, x)}{\partial x} = \varphi(t, x)$ , rate at which persons born at time  $t$  die at age  $x$ , equation (3), p. 331.

$E_x^{t/t_2} = \int_{t_1}^{t_2} f(t, x) dt$ , aggregate of persons surviving to same age, equation (6), p. 332.

$\mu_{x+t} = -\frac{d \log l_{x+t}}{dx}$ , equation (15), p. 336.

$P_x^{t/t_2} = \int_{t_1}^{t_2} f(t, x-t) dt$ , population aggregate or aggregate of persons living at same time, equation (8), p. 333.

$y_x = (1 - c_x)u_x + c_x v_x$ , osculatory interpolation curve, equation (31), p. 344.

Errors, systematic, section 129, p. 361.

Europe, p. 13.

different parts of, represented by life tables, section 9, p. 19.

mortality in, compared with that in other countries, section 41, p. 34; section 87, p. 203.

Expectation of life. *See* Complete expectation of life.

Expected deaths:

deviation of, from actual, pp. 356, 360.

accumulated, p. 360.

equal actual deaths, condition for modified Lagrange formula, equation (63), p. 352.

*See* Deaths.

Explanation of a New Formula for Interpolation, footnote, p. 344.

Exposed to risk of death, determination of, number:

by single years of age under 5 and by months under 1 year, equations (29), (30), pp. 342, 343.

for males in the state of New York, 1910, tables 111, 112, p. 343; tape 145, p. 373.

for ages 5 and over, section 169, p. 386.

for males in the state of New York, 1910, tapes 169 to 171, p. 389; tapes 181 to 183, pp. 391, 393.

$f(t, x)$ , rate at which persons born at time  $t$  survive to age  $x$ , equation (2) and diagram 4, p. 331.

$F(t, x)$ , number of persons born after a fixed time and before time  $t$  who survive to age  $x$ , section 97, p. 330.

Factors to determine—

decedents born in later calendar year, number of, table 109, p. 340.

application of, to deaths in diagram 15, diagram 17, p. 341.

stationary population by single years under 5, equation (52), p. 351.

unit fifth differences for osculatory interpolation by continuous addition, table 130, p. 380. *See also* table 115, p. 347.

*See* Percentage.

Faculty of Actuaries of Scotland, section 90, p. 224.

Females, mortality functions for, compared with those for males. *See* Males.

Fifth difference osculatory interpolation formula—

applied to original statistics grouped in each of the five quinquennial age groups, section 129, p. 356.

derivation of, section 113, p. 344.

fifth difference corrections of, determination of, section 115, p. 346.

derivation of coefficients for, table 114, p. 347.

Figure within a circle, section 138, p. 371.

First year of life, subdivided into age intervals of 1 month, section 17, p. 25. *See* Infant mortality. *See* Months of age under 1 year.

Five, single years of age under, section 84, p. 48; section 95, p. 329.

calculation of—

rates of mortality joining those by, with those by osculatory interpolation, tapes 250 to 263, p. 409.

stationary population by, for males in the state of New York, 1910, tapes 230, 231, 235, p. 405.

deaths by, used in determining number of births, section 275, p. 423.

among males in the state of New York, 1905-1911, table 106, p. 338.

for Massachusetts, 1890, section 276, p. 424.

*See* notes in tables pp. 132 and 138.

*See* Additional mortality statistics used in determining the number of births, pp. 428 to 476.

determination of population by, used in calculation of number of births and of rates of mortality by, among males in the state of New York, tapes 137 to 139, p. 373.

equations for stationary populations by, equations (52), p. 351.

Five, single years of age under—Continued.

number exposed to risk of death by, equations (30), p. 343.

percentages of deaths in calendar year according to later and earlier years of birth for, table 109, p. 340.

rates of mortality by:

calculated by method employed for German life tables, 1891-1900, section 12, p. 20.

computation of, for males in the state of New York, 1910, table 111, p. 343; tapes 143, 145, 146, p. 373.

derivation of general equations for, section 105, p. 336.

method of obtaining, same for each life table, section 125, p. 352.

specific equations for, section 111, p. 342.

reasons for not using original statistics by, in constructing foreign-born white life tables, note in tables, pp. 96 to 103.

Flow of population, section 96, p. 329.

connection between, and time and age, diagram 1, p. 329.

mathematical theory of, section 97, p. 330.

measured by life lines, diagram 2, p. 330.

Force of mortality, section 105, p. 336.

equation for, (15), p. 336.

symbol for,  $\mu_x$ , equation (15), p. 336.

Foreign-born whites in the original registration states, section 2, p. 17.

distribution of deaths among whites of unknown nativity between native whites and, section 277, p. 427.

life tables for, pp. 96 to 103.

radix of, is 100,000 at age 5. *See* tables, pp. 96 to 103.

tabular outline for construction of, p. 416.

original statistics for:

1910, pp. 436, 437.

1901, pp. 460, 461.

belong to types I and II, respectively, section 275, p. 423.

rates of mortality for, very near those of aggregate whites in the original registration states, section 32, p. 31.

Foreign countries, p. 13.

annual rates of mortality in, pp. 204 to 207.

compared, section 9, p. 19; section 41, p. 34; section 70, p. 44.

graphs of, pp. 250, 251.

complete expectation of life in, pp. 216 to 219.

compared, section 53, p. 39; section 73, p. 45.

graphs of, pp. 280, 281.

deaths in, out of 100,000 born alive, number of, pp. 212 to 215.

compared, section 72, p. 44.

graphs of, pp. 270, 271.

measure of vitality in, pp. 220 to 223.

compared, section 74, p. 45.

computed in the Bureau of the Census, footnote, p. 203.

graphs of, pp. 290, 291.

mortality functions shown for, section 69, p. 44; sections 88, 89, p. 203.

epochs of, section 87, p. 203.

graphs of, section 69, p. 44; section 88, p. 203.

tables of, pp. 204 to 223.

tabular form facilitates comparison of, section 89, p. 203.

publications containing life tables of, footnote, p. 203.

survivors in, out of 100,000 born alive, number of, pp. 208 to 211.

compared, section 71, p. 44.

graphs of, pp. 260, 261.

Formulas and processes, special, section 125, p. 352.

Foudray, Elbertie, p. 13.

Four French Offices Mortality Experience. *See* French.

Fourth difference interpolation curve, section 116, p. 347.

equation for leading unit differences of, in terms of leading quinquennial differences, equation (42), p. 347.

Fractional—

ages, section 18, p. 25.

leading, differences in terms of leading integral differences, section 114, p. 345.

derivation of, table 113, p. 346.

equations for, (40), (41), pp. 346, 347.

values, equation for, (39), p. 345.

France:

annual rate of mortality in, pp. 204 to 207.

complete expectation of life in, pp. 216 to 219.

deaths in, out of 100,000 born alive, number of, pp. 212 to 215.

compared, section 72, p. 45.

insured lives in, section 90, p. 224. *See* French Offices Mortality Experience, Four.

measure of vitality in, pp. 220 to 223.

compared, section 74, p. 45.

computed in the Bureau of the Census, footnote, p. 203.

questions and answers concerning, sections 28 to 68, pp. 29 to 44.

headings, section 16, p. 25.

tabular outline for construction of each, section 85, p. 48; section 135, p. 369.

Life tables. *See* Parts II and III.

abridged, short method of calculating, footnote, p. 372.

division of text with reference to use of, section 1, p. 17.

extent of, section 2, p. 17.

for foreign countries, sections 69 to 74, pp. 44, 45. *See also* Insurance companies, mortality tables based on experience of. *See* Part III.

irregularities in, section 7, p. 19; section 12, p. 20.

## Life tables—Continued.

- policy adopted in construction of, section 4, p. 18.  
 populations and reported deaths used in calculation of. *See* heading of each table in Part II.  
 purpose of, section 5, p. 18.  
 special methods used in construction of some, section 134, p. 369.  
 theory of construction of, p. 13; section 12, p. 20. *See* Part VI.
- Limit, age, of human life, section 84, p. 48; section 95, p. 329; section 117, p. 348.
- Lines:  
 diagonal, used to indicate present or current time, the  $z$  lines, section 96, p. 329.  
 horizontal, used to divide series of numbers in groups of fives, tape 161, p. 384; tape 168, p. 387; tape 209, p. 399.  
   used to indicate date of birth, the  $t$  lines, section 96, p. 329.  
   used to indicate junction points in a series of numbers made up of several others, tape 206, p. 397; tape 228, p. 405.  
 to designate graphs of the functions of insurance mortality tables, section 77, p. 46.  
 vertical, used to indicate age, the  $x$  lines, section 96, p. 329.
- Living at same time. *See* Population.
- $m = (re^u - r^u) / (re^u - 1)$ , equation (71), p. 353.  
 $m_x$ , central death rate, equation (24), p. 338; equation (60), p. 352.  
 $M$ , oldest age of life, section 117, p. 348.  
 sum of deaths to age  $x$ , equation (63), p. 352.  
 $M_x$ , commutation column, pp. 302 to 311; pp. 316 to 325.  
 $M_x^h$ , symbol for Seventeen Swedish Offices Life Tables, section 90, p. 225.  
 $\frac{M_x}{M_x^h}$ , ratios defined at beginning of table 127, p. 362.  
 $\frac{M_x}{M_x^h}$ , averaged ratios defined, section 130, p. 364.  
 Makeham's formula, section 94, p. 297.
- Males:  
 complete expectation of life for:  
   change in, between 1901 and 1910 compared with that for females, section 52, p. 38.  
   less favorable than for females, section 7, p. 18; section 49, p. 38; section 73, p. 45.  
 life table functions for, compared with those for females. *See* pages 204 to 223, 250, 251, 260, 261, 270, 271, 280, 281, 290, 291.  
 measure of vitality for:  
   changes in, compared with those for females, section 61, p. 41.  
   monthly, compared with that for females, section 62, p. 42.  
 rates of mortality for:  
   at age 25, compared with those for females, section 31, p. 30.  
   comparison of change in, with that for females, section 34, p. 32.  
   higher than for females, section 37, p. 33.  
   irregularities in, more pronounced than for females, section 36, p. 33.  
   monthly, compared with those for females, section 33, p. 32.  
 survivors among, out of 100,000 born alive, number of:  
   curves of, in diagram of deviation from the mean compared with those for females, section 45, p. 37.  
 Massachusetts, section 2, p. 17; section 12, p. 20; section 29, p. 30.  
 annual rate of mortality in:  
   changes in, from 1890 to 1901 compared with those from 1901 to 1910, section 40, p. 34.  
   characteristic changes in, among males, section 32, p. 31.  
   comparison of change in, among males and among females, section 34, p. 32.  
   graphs of, p. 252.  
   lower among women than among men, section 37, p. 34.  
 average death rate of total population at birth in, section 63, p. 42.  
   change in, section 63, p. 42.  
 birth registration statistics employed in 1901 and 1910 life tables for, section 12, p. 20; section 110, p. 342; section 279, p. 425.  
 births in, in census year of 1890, assumptions made to compute number of, section 110, p. 342; section 276, p. 424.  
   computed number of, and number of, registered, section 279, p. 425.  
 complete expectation of life in:  
   change in, between 1901 and 1910 and between 1890 and 1901, section 52, p. 39.  
   graphs of, p. 282.  
 deaths in, out of 100,000 born alive, number of:  
   graphs of, p. 272.

## Massachusetts—Continued.

- $k = D_s^{(10)} / D_{0/1}^{(10)}$ , percentage factor for deaths under 1 month for 1910 in, section 124, p. 351.  
 life tables for, pp. 132 to 143.  
   only part of the United States represented in 1890, section 2, p. 17; section 40, p. 34.  
   tabular outline for construction of, p. 418.  
 measure of vitality in:  
   change in maximum of, between 1890, 1901, and 1901, 1910, section 61, p. 41.  
   graphs of, p. 292.  
 original statistics for:  
   1910, pp. 444, 445.  
   1901, p. 471.  
   census year ended May 31, 1890, p. 470. *See* footnote.  
   census year ended May 31, 1890, under 1 year of age differ materially from those given in State Reports, note in tables, pp. 132 and 138.  
   belong to types I and VI, respectively, section 275, p. 423.  
 survivors in, out of 100,000 born alive, number of:  
   curves of, for the same sex at different periods, section 45, p. 36.  
   graphs of, p. 262.  
 Mean, deviation from, section 45, p. 36.

numbers of deaths registered, tapes 162 to 168, pp. 385, 387.

by continuous addition of corrected fifth differences, tapes 154 to 158, pp. 377, 381.

calculation of the rates of mortality joining those under 5 with those by, tapes 250 to 263, p. 409.

derivation of equations for, section 126, p. 352.

corrected fifth difference of, equations for, table 115, p. 347.

derivation of the coefficients for, table 114, p. 347.

differentiating for, tapes 147 to 153, pp. 373, 377.

formula for, equations (38), (39), p. 345.

derivation of, section 113, p. 344.

fourth difference interpolation curves employed at beginning and end of, section 116, p. 347.

junction of, table 116, p. 348.

illustrating proof of formula for, diagram 18, p. 345.

quinquennial age group to which, was applied:

for 32 of the United States life tables for which only 5–9 group was available, section 118, p. 349; section 131, p. 364.

for other tables whose populations and deaths were given by single years of age, section 12, p. 20; section 118, p. 349; section 131, p. 364.

investigation preceding selection of, for United States life tables, sections 129, 130, pp. 356 to 364.

## Osculatory fifth difference interpolation—Continued.

- quinquennial age group to which, was applied—Continued.
  - tested by comparing the differences of averaged ratios for populations and for deaths, p. 363.
  - tested by comparison of ratios of population, p. 362.
  - used in construction of each United States life table, column 4, pp. 416 and 418.
  - variation in deviations of expected deaths from actual deaths with, p. 360.
  - variation in rates of mortality with, pp. 357, 358.
  - variation in weighted squared deviations of rates of mortality with, p. 361.
  - variation of third differences of rates of mortality with, p. 359.

## Osculatory Interpolation by Central Differences; with an Application to Life Table Construction, footnote, p. 344.

- Outline, tabular, for construction of each life table, section 85, p. 49; pp. 416 to 419.
  - for calculating operand in Spencer's 21-term formula, table 134, p. 398.
  - used in calculation of rates of mortality joining those under age 5 with those by osculatory interpolation, first, table 118, p. 352.
  - second, table 119, p. 353.
- Overlapping series of rates of mortality, section 120, p. 350.

- $p_x$ , probability of living 1 year from age  $x$ , equation (51), p. 351.
- ${}_t p_x$ , probability that those who have attained age  $x$  will survive to age  $x+t$ , section 105, p. 336.
- $p_x^{t/t+1}$ , probability that those born in interval  $(t, t+1)$  and attaining exact age  $x$  will survive to age  $x+1$ , equation (14), p. 336.
- $P_t$ , total population at time  $t$ , section 127 and equation (67), p. 353.
- $P_x$ , net annual premium at age  $x$  for ordinary whole life insurance of 1, pp. 300, 314.
- ${}_y P_x$ , total population aged  $x$  at time  $y$ , tape 138, p. 373.
- $P_x^{1/2}$ , number of persons at time  $x$  living between the ages  $x_1$  and  $x_2$ , equation (8), p. 333.
- Papps, P. C. H., footnote, p. 358.
- Pennsylvania, section 108, p. 340.
- Percentage factor for deaths under 1 month in 1910, section 124, p. 351.
  - calculation of, for state of New York, table 117, p. 351.
  - equation for,  $k = D^{(12)} / D_{0/12}^{t/t+1}$ , section 124, p. 351.
- Percentage of decedents born in—
  - earlier and later calendar years—
    - derived from German mortality statistics, section 107, p. 339.
    - employed for computing births for United States life tables, table 109, p. 340.
    - graduated, based on deaths in Prussia, table 107, p. 339.
  - earlier calendar month, based on mortality statistics for 1910 in Massachusetts, New York, New York City, and the original registration states, section 124, p. 351.
  - calculated for the state of New York, 1910, table 117, p. 351.
  - used in calculation of derived functions in United States life tables, section 124 and equation (54), p. 351.
  - later calendar year, based on mortality statistics of German states in 1910 and 1911, table 108, p. 339.
  - formula to obtain, when intervals of time are months, equation (28), p. 340.
  - method employed to verify, section 108, p. 339.

## Period:

- equation for the determination of mean population of—
  - a subdivision of total population of any, equation (74), p. 354.
  - total population of any, equation (75), p. 354.
- observation, p. 334. *See* Interval.

## Periods of—

- deaths upon which United States life tables were based, section 2, p. 17.
- experience upon which mortality tables of insurance companies are based, section 90, p. 224.
- life tables of foreign countries shown, section 69, p. 44; section 87, p. 203.

## Perozzo, footnote, p. 329.

## Philadelphia, section 2, p. 17.

- births in, computed number of, and number of, registered, p. 425.
- registered, used in construction of 1910 life tables of, section 12, p. 20; section 110, p. 342; section 279, p. 426.

## Philadelphia—Continued.

- deaths by days and weeks, 1910, 1911 in, used in drawing infant mortality curves for cities, table 129, p. 364.
- life tables for, pp. 192 to 199.
  - tabular outline for construction of, p. 418.
- maximum measure of vitality in, increase in, between 1901 and 1910, section 61, p. 41.
- original statistics for, p. 476.
  - belong to type VII, section 275, p. 424.
- Physicians, life tables of service to, p. 13.
- $\pi_t$ , any subdivision of population at time  $t$ , equation (68), p. 353.
- $\bar{\pi}_t$ , mean value of any subdivision of the population during the period  $t$ , equation (74), p. 354.
- Pivotal values, section 118, p. 349.
- Population:
  - actual, average annual death rate in, section 64, p. 42.
    - comparison of, with that in stationary population, section 65, p. 43.
  - aggregate of, sections 99, 100, pp. 332, 333. *See* Aggregate of those living at same time.
  - birth and age intervals covered by, living at same time, diagram 7, p. 333.
  - determination of, used in calculation of number of births, of annual rates of mortality under 5 years, and of monthly rates of mortality under 1 year, sections 137 to 139, pp. 370, 371.
  - distribution of, into subdivisions by percentage factors  $m$  and  $n$ , section 127, p. 353.
    - aged 100 years and over into single years of age by proportion, tape 265, p. 409; section 276, p. 424.
    - of unknown ages, section 277, p. 424.
  - enumeration of, in the United States, section 100, p. 333.
  - estimates of, section 278, p. 424.
    - by arithmetic progression, section 256, p. 408.
    - by geometric progression, section 127, p. 353; sections 137 to 139, p. 370.
  - flow of, graphic representation of, section 96, p. 329, diagrams 1, 2, and 4, pp. 329, 330, 331.
    - mathematical theory of, section 97, p. 330.
  - in current age interval. *See* Stationary population.
  - in current and all older age intervals. *See* Stationary population.
  - largest and smallest, for which a life table was calculated, section 2, p. 17.
  - mean, determination of, section 127, p. 353.
    - calculation of, for 1901–1910 of white females in the original registration states, tapes 264 to 274, pp. 411, 412, 414.
    - general equations for, (74), (75), p. 354.
    - specific equations for, (76), (77), p. 354.
  - per death in age interval. *See* Measure of vitality.
  - stationary. *See* Stationary population.
  - total, defined, section 24, p. 28. *See* Stationary population.
  - under 2 years not employed to calculate number of births, section 110, p. 342.
- Premiums, net, pp. 300, 314.
  - at different rates of interest, section 94, p. 297.
  - based on life tables for white males and for white females in the original registration states, 1910, section 11, p. 20; sections 93, 94, p. 297.
  - conform closely to present mortality conditions, section 11, p. 20; sections 93, 94, p. 297.
  - equations for, pp. 300, 314.
  - practical use served by, sections 93, 94, p. 297.
  - questions and answers concerning, section 83, p. 47.
  - symbols for—
    - annual,  $P_x$ , pp. 300, 314.
    - single,  $\Lambda_x$ , pp. 300, 314.
- Prussia, deaths in, table 107, p. 339.
- Public health officials, life tables of service to, p. 13.
- $q_x$ , annual rate of mortality at age  $x$ , probability that a person living at exact age  $x$  will die within a year, section 20, p. 26; equations (16), p. 336; (22), p. 337; (43), p. 348; (91), p. 410.
- $q_x^{(12)}$ , monthly rate of mortality at age  $x$ , probability that a person living at exact age  $x$  will die within a month, section 20, p. 26; section 33, p. 31; table 112, p. 343.
- $q_x^{t/t+1}$ , rate of mortality at age  $x$  of those born in the interval  $(t, t+1)$ , equations (14), p. 336; (24), p. 338.
- $oq_x$ , observed annual rate of mortality, p. 357.

Questions and answers illustrating use of tables and graphs, section 6, p. 18; sections 27 to 86, pp. 29 to 49.

concerning—

complete expectation of life, sections 49 to 53, pp. 37 to 39.  
death rate per thousand, sections 63 to 68, pp. 42, 43.  
deaths, number of, sections 47, 48, p. 37.  
life tables of foreign countries, sections 69 to 74, pp. 44, 45.  
measure of vitality, sections 58 to 62, pp. 40, 41, 42.  
mortality tables of insurance companies, sections 75 to 82, pp. 45 to 47.

Parts V to VIII, sections 83 to 86, pp. 47 to 49.

rates of mortality, sections 28 to 41, pp. 29 to 35.

stationary population, sections 54 to 57, pp. 39, 40.

survivors, number of, sections 42 to 46, pp. 35 to 37.

total stationary population, section 57, p. 40.

scope and purpose of, section 27, p. 29.

Quinquennial age groups, section 118, p. 349.

rates of mortality at older ages determined—

by applying Wittstein's formula to the averaged rates from all five, sections 117, 119, pp. 348, 349.

from populations and deaths graduated from the original statistics grouped in all five, section 118, p. 349; tapes 174 to 187, pp. 389, 391, 393.

ratio test for concentration in, section 130, p. 362.

selection of, for osculatory interpolation, important, section 129, p. 356.

for the United States life tables, section 131, p. 364.

tested by comparison of—

differences of averaged ratios for populations and for deaths, p. 363.

ratios for populations, p. 362.

variation of rates of mortality with the, of original statistics to which osculatory interpolation formula is applied, section 129, p. 356.

various rates of mortality obtained from the same original statistics by applying interpolation formula to different, of population and mortality statistics, p. 357.

deviations of expected deaths according to the, from the actual deaths, p. 360.

deviations of the, from those in the average group, p. 358.

third differences of the, p. 359.

weight squared deviations of the, from the observed rates, p. 361.

Quinquennial differences:

first five leading, of  $T_x$  and  $l_x$ :

calculation of, for males in the state of New York, 1910, tapes 147 to 152, pp. 375 and 377.

method of obtaining, section 149, p. 374.

required for osculatory interpolation, section 149, p. 374.

first three, of  $T_x$  and  $l_x$  at older ages:

calculation of, from each quinquennial age group for males in the state of New York, 1910, tapes 174 to 178, pp. 389 to 391.

required for graduation by 15-term formula, section 118, p. 349.

leading unit differences derived from leading, according to fifth difference osculatory interpolation curve:

calculation of, for  $T_{90}$  and  $l_{90}$ , tape 155, p. 377; tapes 162, 163, p. 385.

equations for, (80), p. 376.

ten years younger, section 155, p. 376.

leading unit differences derived from leading, according to fourth difference interpolation curve:

calculation of, for  $T_4$  and  $l_4$ , tape 154, p. 377; tapes 162, 163, p. 385.

equations for, (79), p. 376.

of same age, section 154, p. 376.

selection of rates of mortality upon which to base Wittstein's constants determined from, of rates of mortality, section 188, p. 392.

r, geometric rate of increase of population, equation (66), p. 353; equation (78), p. 370.

R in column 3 of table 135 indicates that the number of births registered were used in the construction of the life table, p. 418.

$R_x$ , commutation column, pp. 302 to 311, 316 to 325.

Radix of—

life tables for foreign-born whites in the original registration states, note in tables, pp. 96 to 103.

Radix of—Continued.

mortality tables of insurance companies, common, section 91, p. 225.

original, section 79, p. 46; section 80, p. 47; section 91, p. 225; pp. 236 to 239.

United States life tables, section 123, p. 351; section 229, p. 404.

Rate—

at which persons born at time  $t$ —

die at age  $x$ , equation (3), p. 331.

survive to age  $x$ , equation (2), p. 331.

average annual death. See Death rate.

variation of, with time and with age, diagram 3, p. 331.

Rate of mortality, p. 13.

age at which, equals that at birth, section 41, p. 35.

among both sexes, 1910, in the original registration states, section 28, p. 29.

among foreign people, pp. 204 to 207.

graphs of, pp. 250, 251.

questions and answers concerning, section 70, p. 44.

among infants, section 30, p. 30; section 33, p. 31. See INFANT MORTALITY, column 4 in tables of Part II.

among insured lives, p. 226.

graphs of, p. 253.

questions and answers concerning, section 78, p. 46.

annual, section 28, p. 29.

calculation of, by months under 1 year, section 132, p. 364.

under 1 year, section 30, p. 30.

at advanced ages, calculation of, for males in the state of New York, 1910, tapes 174 to 228, pp. 389, 391, 393, 397, 399, 403, 405.

methods used in calculation of, section 117 to 121, pp. 348 to 350.

values for, influenced by hypothesis, section 31, p. 31.

calculation of, for males in the state of New York, 1910. See New York, males in the state of, 1910.

joining those under age 5 with those by osculatory interpolation for white females in cities of original registration states, 1901, tapes 250 to 263, p. 409.

changes in:

among males in New York City between 1901 and 1910, section 31, p. 30.

characteristic, among males, section 32, p. 31.

least between ages 20 and 40, section 38, p. 34.

most rapid during the first few days of life, section 38, p. 34.

comparative, section 31, p. 30.

comparison of, among whites and Negroes, section 39, p. 34.

among women and among men, section 37, p. 33.

for native whites with that for foreign-born whites, section 32, p. 31.

in United States with that in other countries, section 41, p. 34.

urban and rural, section 35, p. 33.

comparison of change in, among men and among women, section 34, p. 32.

from 1890 to 1901 with that from 1901 to 1910, section 40, p. 34.

decrease in, at birth between 1901 and 1910 greater—

among males than among females, section 34, p. 32.

among Negroes than among whites, section 32, p. 31.

in Massachusetts than among other whites, section 32, p. 31.

deviation of, for each quinquennial age group from that for the average group in table 122, table 123, p. 358.

expected deaths according to graduated, in table 122 from actual deaths, p. 360.

explanation of, section 20, p. 26.

expression of, in terms of—

aggregates of the living and of the dead, equations (14), p. 336; (22), p. 337.

central death rate, equations (24), p. 338; (91), p. 410.

force of mortality, equation (16), p. 336.

statistical aggregates, equation (24), p. 338.

Wittstein constants, equation (85), p. 396.

graduation of. See Graduation.

graphical representation of, section 29, p. 29.

graphs of, pp. 243 to 253.

highest, shown in United States is among Negroes, section 39, p. 34.

next, in Massachusetts in 1890, section 40, p. 34.

least favorable, countries showing, section 41, p. 35; section 70, p. 44.

from ages 17 to 29, countries showing, section 70, p. 44.

## Rate of mortality—Continued.

- lowest:
- age at which, generally occurs, section 28, p. 29; section 41, p. 35.
  - among rates shown in this volume, section 70, p. 44.
  - at birth among countries shown herein, section 70, p. 44.
  - monthly, section 33, p. 31.
  - calculation of, by days and weeks under 1 month, section 132, p. 364.
  - increase in, at birth between 1901 and 1910, section 33, p. 32; section 34, p. 33.
  - questions and answers concerning, section 30, p. 30; section 33, p. 31. *See* Infant mortality.
  - most favorable at age 50, countries showing, section 70, p. 44.
  - observed, section 129 and note in heading of table, p. 357.
  - weighted squared deviations of graduated rates of mortality from, p. 361.
  - overlapping series of, section 120, p. 350.
  - per thousand. *See* column 4 of tables in Part II. *See also* pp. 204 to 207, 226.
  - questions and answers concerning, sections 28 to 41, pp. 29 to 35.
    - among infants, section 30, p. 30; section 33, p. 31.
    - among insured lives, section 78, p. 46.
    - among whites and Negroes, section 39, p. 34.
    - for males and females, section 34, p. 32; section 37, p. 33.
    - for native whites and foreign-born whites, section 32, p. 31.
    - in foreign countries, section 70, p. 44.
    - in 1890-1901 and in 1901-1910, section 40, p. 34.
    - in United States and in other countries, section 41, p. 34.
    - urban and rural, section 35, p. 33.
  - relation between, and measure of vitality, section 58, p. 41.
  - shape of curve of, section 29, p. 29.
  - significant irregularities in, section 36, p. 33; section 37, p. 34.
  - among insured lives, section 78, p. 46.
  - greater among Negroes than among whites, section 39, p. 34.
  - summary of methods employed to obtain, section 122, p. 350.
  - symbol for,  $q_x$ , section 20, p. 26. *See* heading of column 4 in tables of Part II.
  - tested for smoothness and conformity to original statistics, section 128, p. 354.
  - third differences of graduated, in table 122, table 124, p. 359.
  - among whites in the original registration states, 1910, p. 355.
  - under age 5. *See* Five, single years of age under.
  - junction of, with those by osculatory interpolation, section 126, p. 352.
  - under 1 year, section 30, p. 30; section 33, p. 31. *See* INFANT MORTALITY, column 4, in tables of Part II.
  - variation of, with age, section 38, p. 34.
  - with number of deaths and number of survivors, section 48, p. 37.
  - with quinquennial age groups of statistics to which osculatory interpolation formula is applied, section 129, p. 356.

$t$ , abscissa on time axis, section 96, p. 329.

$T_x$ , stationary population at age  $x$  and in all older age intervals, section 24, p. 28; equation (56), p. 352.

## Table of—

- ages and sources of data for construction of each United States life table, p. 416.
- births, computed number of, and number of, registered, p. 425.
- computation of rates of mortality—
  - by months of age under 1 year, table 112, p. 343.
  - by single years under age 5, table 111, p. 343.
  - joining those under age 5 with those by osculatory interpolation, first, table 118, p. 352; second, table 119, p. 353.
- determination of percentage of decedents who were born in earlier calendar month, table 117, p. 351.
- deviations of rates of mortality for each quinquennial age group from those in average group, p. 358.
- equations for leading fractional differences in fifth difference osculatory interpolation, table 113, p. 346; table 114, p. 347.
- factors for unit fifth differences used in joining fourth and fifth difference interpolation curves in interpolating by continuous addition, table 116, p. 348.
- mechanical process for obtaining operand of Spencer's 21-term formula, table 134, p. 398.
- rates of mortality obtained from different quinquennial age groups, p. 357.
- ratio test for different quinquennial age groups, p. 362.
- averaged, p. 363.
- weighted squared deviation of graduated rates of mortality from observed rates of mortality, p. 361.

Table Suisse de Survie pour les années 1901-1910, footnote, p. 203.

## Tables of—

- deviations of expected deaths from actual deaths, pp. 356, 360.
- differences between, rates of mortality based on experience of insurance companies and those based on census statistics, section 76, p. 46; section 92, p. 225.
- life, the United States, pp. 52 to 199.
- mortality functions—
  - based on experience of insurance companies, pp. 226 to 239.
  - from life tables of foreign countries, pp. 204 to 223.
  - from truncated life tables, section 90, p. 224.
- mortality statistics:
  - additional, used in drawing graphs, table 129, p. 364.
  - used in computing number of male births in the state of New York for 1910, table 106, p. 338.
- original data upon which United States life tables are based, pp. 428 to 476.
- percentages of decedents who were born in earlier or later calendar years, tables 107 to 109, pp. 339, 340.
- third differences of rates of mortality, pp. 355, 359.
- unit fifth differences illustrating interpolation by continuous addition, tables 130 to 133, pp. 380, 382.

Tapes, descriptive text and photographed, section 133, p. 369.

## Tapes showing calculation of—

- derived functions for males in the state of New York, 1910, tapes 228 to 236, p. 405; tapes 240 to 243, p. 407.
- mean population of white females in the original registration states, 1901-1910, tapes 264 to 274, pp. 411, 412, 414.
- rates of mortality for males in the state of New York, 1910—
  - ages 0 to 4, including monthly rates under 1 year, tapes 137 to 146, p. 373.
  - ages 4 to 109, by osculatory interpolation, tapes 147 to 173, pp. 373, 377, 381, 384, 385, 387, 389.
  - ages 80 to 105, smoothed by Spencer's 21-term formula, tapes 206 to 227, pp. 397, 399, 403, 405.
  - ages 89 to 105, by averaging rates from different groups, tapes 174 to 187, pp. 389, 391, 393.
  - ages 94 to 115, by Wittstein's formula, tapes 188 to 205, pp. 393 and 397.
- reg graduation of rates of mortality for white females in cities of the original registration states, 1901, between ages 3 and 13, by Lagrange's formula modified, tapes 250 to 263, p. 409.

Tavole di Mortalità della Popolazione Italiana, footnote, p. 203.

Teikoku, section 90, p. 224.

Test for different quinquennial age groups, ratio, pp. 362, 363.

Theorem, Green's, section 98, p. 332.

Lagrange's, section 126, p. 352.

of the mean, section 105, p. 337.

Theorems, two important, section 98, p. 331.

Third differences of rates of mortality, pp. 355, 359.

Time axis, section 96, p. 329.

Total population, defined, section 24, p. 28.

Totals, absolute, net, negative, and positive, defined, section 128, p. 354.

## Totals of—

deviations of expected deaths from actual deaths—

ages 15 to 85 and 28 to 77, p. 360.

all ages and all ages excluding 0-1 and 1-2, p. 356.

deviation of rates of mortality for each quinquennial age group from that for the average group in table 122, table 123, ages 15 to 85 and 28 to 77, p. 358.

third differences of rates of mortality—

ages 15 to 85 and 28 to 77, p. 359.

all ages and all ages excluding 0-1 and 1-2, p. 355.

weighted squared deviations of graduated from observed rates of mortality, ages 15 to 85 and 28 to 77, p. 361.

Transactions of the Second International Actuarial Congress, footnote, p. 344.

Truncated mortality tables, mortality functions derived from, section 90, p. 224.

29-term osculatory interpolation formula, section 129, and note to heading of table 122, p. 357.

21-term formula, Spencer's, section 12, p. 20; sections 121 and 122, p. 350; section 125, p. 352.

rates of mortality smoothed by, tapes 206 to 227, pp. 397, 399, 403, 405.

Twenty-three German Offices Mortality Experience. *See* German Offices Mortality Experience, Twenty-three.

Types, seven, of original statistics, section 275, p. 423.

three, of aggregates of the dead, sections 101 to 103, pp. 333 334.

two, of aggregates of the living, sections 99, 100, pp. 332, 333.

$u$ , unit of time on which constant  $r$  is based, equation (66), p. 353.

function whose central value is graduated by the 15-term formula, section 118, p. 349.

$u_x$ , fourth degree interpolation curve, equation (32), p. 344.

function of the age variable  $x$ , table 118, p. 352.

equals  $10^6 q_x + 7$ , tape 207, p. 399.

$u_0$ , central values smoothed by Spencer's 21-term formula from the 10 ungraduated values before and the 10 ungraduated values after it, equation (50), p. 350.

$U = U_a + U_b + U_c$ , equation (62), p. 352.

$U_x = m_x / u_x v_x$ , table 118, p. 352.

operand in Spencer's 21-term formula, tape 209, p. 399.

## Unit differences:

equations for corrected fifth, equation (81), p. 380.

instructions for using, to interpolate by continuous addition, section 158, p. 378.

leading fractional differences for fifth differences osculatory interpolation in terms of leading, equation (40), p. 346.

leading, for fifth difference osculatory interpolation curve in terms of leading quinquennial differences:

calculation of, by continuous addition, tapes 158 to 161, pp. 383, 384; tapes 165 to 168, pp. 385, 387.

calculation of, for  $T_{99}$  and  $l_{99}$ , to serve as checks, tape 155, p. 377; tapes 162, 163, p. 385.

equation for, (80), p. 376.

leading, for fourth difference interpolation curve in terms of leading quinquennial differences, equation (42), p. 347.

calculation of, for  $T_4$  and  $l_4$ , to start the continuous addition, tape 154, p. 377; tapes 162, 163, p. 385.

equation for, rearranged for convenience of computer, equation (79), p. 376.

used in reg graduation of rates of mortality joining infant mortality with osculatory interpolation curves, section 126, p. 353.

general equations for initial, (65), p. 353.

obtained by continuous addition, tapes 260 to 262, p. 409.

specific equations for initial, (90), p. 410.

United States, description of mortality tables based on insured lives in, section 90, p. 224.

United States life tables, 1890, 1901, 1910, and 1901-1910, p. 13; Part II.

construction of:

- mathematical theory of, p. 13; section 12, p. 20; Part VI.
- numerical processes of, described by detailed construction of one life table, p. 13; section 13, p. 21; Part VII.
- questions and answers concerning, sections 84, 85, p. 48.
- selection of quinquennial age group for, section 131, p. 364.
- variations from standard, section 14, p. 21; p. 416; tapes 250 to 274, pp. 409, 412, 414.

divided into three groups, original registration states, selected registration states, selected registration cities, pp. 4 and 5.

graphs of functions of, section 8, p. 19; Part IV.

life table functions of foreign countries and those based on experience of life insurance companies included to compare with, p. 13; Part III.

questions and answers concerning, sections 69 to 82, pp. 44 to 47.

measure of vitality in, compared with that in foreign countries, section 74, p. 45.

monetary values based on, p. 13; section 11, p. 20; Part V.

questions and answers concerning, section 83, p. 47.

nontechnical description and explanation of, Part I.

rates of mortality in, compared with those among insured lives, section 78, p. 46.

statistics for:

- furnished by Bureau of the Census, p. 13; section 15, p. 21.
- include enumerated and estimated populations, reported deaths, and birth registration statistics, section 15, p. 21.
- original, are all given, p. 13.
- questions and answers concerning, section 86, p. 49.
- tabular outline for construction of each of the, pp. 416 to 419.
- use of, p. 13.
- what they show, p. 13; section 7, p. 18.

University of Michigan, p. 13.

Unknown:

- ages, distribution of population and mortality statistics of, section 277, p. 424.
- nativity, distribution of population and mortality statistics of, section 277, p. 424.

Urban. *See* Cities.

meaning of, as used in the life tables, section 280, p. 426.

$$v_x = e^{\int_0^x \mu_x + \epsilon d\epsilon}, \text{ section 105, p. 337.}$$

$$v_x = \sum_{x-3}^{x+3} U_x, \text{ tape 212, p. 399.}$$

fourth degree interpolation curves, equation (33), p. 344.

in terms of  $u_x$ , equation (34), p. 344.

function of age variable  $x$ , table 118, p. 352.

$$V = (c+f)U_a + fU_b + eU_c, \text{ table 118, p. 352.}$$

$$V_x = \sum_{x-2}^{x+2} w_x, \text{ tape 218, p. 403.}$$

Variable, independent and dependent, section 105, p. 336.

Variation—

- in age of those living at same time, section 100, p. 333.
- in time of those living to same age, section 99, p. 332.

Vega's seven place logarithm tables, section 138, p. 370.

Vermont, section 2, p. 17.

Vertical line used to indicate—

- current age, the  $x$  line, section 96, p. 329.
- either decimal point or to cross out extra figures, section 138, p. 370.

Vitality. *See* Measure of vitality.

Vital Statistics, Division of, p. 13; sections 277, 278, p. 424.

$$w_x = \sum_{x-4}^{x+4} u_x, \text{ equation (44), p. 349.}$$

$$= v_{x+5}, \text{ tape 216, p. 403.}$$

weighted squared deviations,  $P_x(q_x - oq_x)^2 / p_x q_x$ , section 129, p. 361.

Wahrscheinlichkeitsrechnung, footnote, p. 329.

Wales, Census of England and, 1911, footnote, p. 364.

Waters, Alfred C., footnote, p. 353.

Weighted squared deviations of graduated rates of mortality from observed rates of mortality in table 122, table 126, p. 361.

equation for, section 129, p. 361.

Whites in the original registration states, section 2, p. 17.

average annual death rate per thousand between ages 20 and 40 among, compared with that for Negroes, section 66, p. 43.

births among, computed number of, p. 425.

complete expectation of life among:

- compared with that among Negroes in 1910, section 53, p. 39.
- graph of, males, 1910, with those for insured lives, p. 283.
- graphs of, 1901-1910, with those for foreign countries, pp. 280, 281.
- graphs of, 1190, with those for Negroes, p. 278.

deaths among, out of 100,000 born alive, number of:

- deviation of expected from actual, 1910, in table 121 is a test for conformity to original statistics, section 128, p. 355.
- graph of, males, 1910, with those for insured lives, p. 273.
- graphs of, 1901-1910, with those for foreign countries, pp. 270, 271.
- graphs of, 1910, with those for Negroes, p. 268.

graphs of life table functions of, section 8, p. 19.

males, 1910, with those for insured lives, section 77, p. 46.

1901-1910, with those for foreign countries, section 69, p. 44.

life tables for, pp. 64 to 75.

males, 1910, compared with those for insured lives, section 90, p. 224; pp. 226 to 235.

males, 1910, used to illustrate the explanation of life table headings in Part II, section 16, p. 25.

1901-1910, compared with those for foreign countries, sections 69 to 74, pp. 44, 45; section 87, p. 203; section 127, p. 353; pp. 204 to 223.

1910, used as basis for commutation columns, annuities, and premiums in Part V, section 11, p. 20; section 83, p. 47; sections 93, 94, p. 297.

tabular outline for construction of, p. 416.

mean populations for, 1901-1910, columns 4 and 9, pp. 464, 465.

computation of, females (tapes 264 to 274, pp. 409, 412, 414) used to illustrate the method, section 134, p. 369.

derivation of equations for, section 127, p. 353.

measure of vitality among:

- graph of, males, 1910, with those for insured lives, p. 293.
- graphs of, 1901-1910, with those for foreign countries, pp. 290, 291.
- graphs of, 1910, with those for Negroes, p. 288.
- monthly, females, 1910, section 62, p. 42.
- 1901-1910, compared with those in foreign countries, section 74, p. 45.

original statistics for:

- 1910, pp. 430, 431.
- 1901, pp. 454, 455.
- 1901-1910, pp. 464, 465.
- belong to types I, II and IV, respectively, section 275, p. 423.

population of, total stationary, compared with that for Negroes, section 56, p. 40.

rate of mortality among:

- graph of, males, 1910, with those for insured lives, p. 253.
- graphs of, 1901-1910, with those for foreign countries, pp. 250, 251.
- graphs of, 1910, with those for Negroes, p. 248.
- 1901-1910, compared with those for foreign countries, section 41, p. 34; section 70, p. 44.
- 1910, compared with those for insured lives, section 78, p. 46.
- 1910, compared with those for Negroes, section 39, p. 34.
- third differences of, 1910, in table 120 is a test for their smoothness, section 128, p. 354.

survivors among, out of 100,000 born alive, number of:

- graph of, males, 1910, with those for insured lives, p. 263.
- graphs of, 1901-1910, with those for foreign countries, pp. 260, 261.
- graphs of, 1910, with those for Negroes, p. 258.
- per cent of, from age 20 to age 62, section 42, p. 35.
- variation in form of curve of, section 46, p. 37.

*See* Cities of the original registration states, whites in.

*See* Foreign-born whites.

*See* Native whites.

*See* Rural part of the original registration states, whites in.

*See* White races.

White people. *See* White races.

White races:

- age at which—
- generation is reduced by one-half among, section 42, p. 35.
- maximum expectation of life occurs among, section 50, p. 38.

## White races—Continued.

- age—  
 distribution of the stationary population among, section 55, p. 40.  
 interval in which the greatest number of deaths occurs among, section 47, p. 37.  
 average death rate of total population at birth in stationary population of, section 63, p. 42.  
 complete expectation of life among:  
 at birth, section 49, p. 38.  
 range of maximum, section 50, p. 38.  
 measure of vitality among:  
 changes in maxima of, in the United States between 1901 and 1910, section 61, p. 41.  
 greatest maximum and least maximum, section 60, p. 41.  
 variation in form of curve of number of survivors among, section 46, p. 37.
- Whole life insurance:  
 British Offices Life Tables, 1863-1893, based on participating, on men, section 90, p. 224.  
 Seventeen Swedish Offices Life Tables not based on, section 90, p. 225.
- Wittstein—  
 graduation joined to osculatory interpolation by Spencer's 21-term formula, section 12, p. 20; section 117, p. 348.  
 old age curve joins fifth difference osculatory curve at various ages, section 14, p. 21; section 134, p. 369; column 16, p. 417.

- Wittstein's formula, modification of, for obtaining rates of mortality at advanced ages, section 12, p. 20; section 117, p. 348.  
 application of, to obtain the rates of mortality for males in the state of New York, 1910, tapes 187 to 205, pp. 393, 397.  
 based on an hypothesis as to the variation of rate of mortality as the age limit of life is approached, section 120, p. 350; section 205, p. 398.  
 employed in calculation of each life table, section 125, p. 352.  
 equations for constants in, (48), (49), p. 349.

$x$ , abscissa on age axis, section 96, p. 329.

$y=f(l, x)$ , equation (2), p. 331.

$=x-a$ , new age variable, section 126, p. 352.

$y_x$ , fifth difference osculatory interpolation curve, equation (31), p. 344.

$=\sum_0^{x-1} u$ , section 118, p. 349.

Young, Allyn A., footnote, p. 362.

$z$ , age variable,  $n+2+x$ , equation (39), p. 345.

$z$ , present or current time,  $x+l$ , section 96, p. 329.

Zeuner, footnote, p. 329.
